At page 555 there is this passage: "Cause of death. The older experimenters attributed death from the inflation of air into the veins, to distention of the right side of the heart, arresting its contractions; and some of them compared its condition to that of the bladder when over distended with urine. Bichat maintained that death begins at the brain, and depends upon the circulation of frothy blood in the vessels of that organ. Nysten, Cormack, and Amussat have referred the death to the mechanical distention of the right side of the heart. Leroy, and Piédagnel attributed it chiefly to emphysema of the lungs. Sir Charles Bell believed that the air, by circulating in the vessels of the medulla oblongata, annihilated the functions of that important portion of the central organs of the nervous system, and thus killed by arresting the respiratory muscular movements. Marchel de Calvi supposes that death is due to the action of the carbonic acid contained in the air,—a supposition which could be readily disproved by a reference to some of Nysten's experiments. Bouillaud, in his report to the Academy, attributes the death partly to the distention of the right side of the heart, and partly to the difficulty of transmitting the frothy blood through the lungs; and Mr. Erichsen refers it entirely to the latter of these two causes. Wattmann (p. 70) gives at some considerable length his explanation of the cause of death, which is much too long to transcribe. He attributes it partly to the disturbance and enfeeblement of the contractibility of the heart, occasioned by the mechanical effects of the air in its cavities, partly to the derangement of the respiratory function; and partly to the circulation of blood mixed with air in the capillary vessels of the systemic circulation being unable to maintain the nutrition, and the vitality of the tissues, especially of such important organs as the brain, the spinal cord, the lungs, and the heart. We do not think it necessary to enter into any critical examination of the arguments advanced by the supporters of these different explanations of the cause of death, as the account which we have already given of the appearances observed after death, and the symptoms which precede it, but more especially the former enables us to select the true one. As in almost all cases in dogs, in the majority of rabbits, and in individuals of the human species, and in a considerable number of horses and sheep killed either by the forced or the spontaneous entrance of air into the veins, no air was found in the left side of the heart, or in the arterial system, it is perfectly obvious that in all these cases the circulation of air in the arteries of the brain, and in the medulla oblongata, could not be the cause of death; for a thing which did not exist could not act. The theories of Bichat and Sir Charles Bell cannot therefore explain the cause of death in all or even the greater number of cases, and there is no evidence in their favour, even in those cases where air was found in the left side of the heart, and in the arterial system, for in all these the right side of the heart was on an average not less distended with air or frothy blood, and the death was not more rapid than when the air was entirely confined to the right side of the heart and the venous system."

Then on page 44 he says: "Since the above memoir was published, Mr. Erichsen (Edinburgh Medical and Surgical Journal, January 1845, vol. 63,) has given us the results of an extensive and careful experimental enquiry into the pathology and treatment of asphyxia, and he confirms the accuracy of all my experiments and observations on this subject, as far as he has repeated them. The amount of increase in the force with which the heart drives the blood along the arteries for a short time after an animal becomes insensible in asphyxia, will, I believe, be found to correspond nearly in both our experiments, when the difference in the form of the hemadynamometers used is taken into account. But while Mr. Erichsen does not object to my data, he dissents from one part of the theory of asphyxia deduced from them. We agree entirely in our explanation of the cause of the suspension of the sensorial functions, in fact, he has been pleased to say that he does 'not feel called upon to make any remarks on this point, as it has already been fully and ably investigated' in the above memoir; but we differ in our explanation of the arrestment of the circulation of the blood through the lungs. I have adopted the opinion that this is due to the cessation of the chemical changes between the blood and atmospheric air in the lungs; while Mr. Erichsen supposes that it depends upon the venous blood acting as an excitant upon the contractility of the ultimate ramifications of the pulmonary veins, and thus causing an obstruction to its passage along these vessels. This view of the cause of the accumulation of the blood in the pulmonic heart and its vessels, adopted by Mr. Erichsen, appears to be incompatible with some well established facts."

Then on page 46 occurs this passage: "Notwithstanding, therefore, all that Mr. Erichsen has so ingeniously advanced against the part of the theory of asphyxia that refers the impediment to the passage of the blood through the lungs to the cessation of the chemical changes which occur there in natural respiration, my belief in its truth has not been shaken."

It is often said that, in these experiments the animals do not feel. I will read a few statements made by Dr. Reid himself in regard to his own experiments, on page 69: "When the glosso-pharyngeal was pricked with the forceps, the indications of suffering were distinctly but not strongly manifested, but the application of a tight ligature was evidently attended by intense pain, an effect which we were somewhat surprised to find also attended the application of a tight ligature to the hypoglossal."

Then on page 73; "With the exceptions mentioned, very severe indications of suffering, and in a few cases also distinct muscular twitching of the neck and face attended the pinching and cutting of this nerve." That is headed "*Experimental investigation into the functions of the eighth pair of nerves.*"

Then on page 92: "I have exposed the trunk of the *par vagum* in the neck, in at least 30 animals, and in almost all of these, the pinching, cutting, and even the stretching of the nerve were attended by *indications of severe suffering.*" Those words "indications of severe suffering" he has placed in italics himself. "It was frequently difficult to separate the nerve from the artery, on account of the violent struggles of the animal, though some of them had been pretty quiet during the previous part of the operation."

Then on page 169 occurs the following passage: "As statements such as those of Mr. Brachet are, however, more effectually met by facts than by arguments," (I should say, I believe Mr. Brachet was considered one of the most eminent medical practitioners and scientific men of France in his day), "I proceeded to put them to the test of experiment. These experiments were seven in number, and six of them were made in the following manner: The vagi and sympathetics, and in some cases the recurrents also, were cut in the middle of the neck, and a portion of each removed. At a longer or shorter period after

Mr. G. R. Jesse.

6 Nov. 1875.

the operation, the pulsations of the heart were reckoned when the animal was lying or standing on the ground, and after it had been caressed for some time to calm its fears. It was then lifted up on the table on which it had been previously tied and operated upon, and after having been spoken to harshly the pulsations were again reckoned. After being again caressed for some time, the pulsations were counted a third time, and when replaced upon the ground they were reckoned a fourth time. The following results were obtained: In the first dog the pulsations of the heart were about 140 before the commencement of the experiment. The animal at this time was apparently somewhat alarmed. Four hours and a half after division of the nerves, the pulsations of the heart were about 170 when the animal was standing on the ground, and rose to 200 at least when placed upon the table. After it was replaced on the ground they had again fallen to about 170. After 19 hours the pulsations were 160 on the ground; they rose again to about 200 when placed on the table, again fell to about 160 when still on the table, and were not increased by being replaced on the ground. In the second dog the pulsations were 156 on the floor, and about 190 on the table; and in the third dog they rose 20 beats in the minute when placed on the table. In both of these two last experiments the pulsations of the heart soon subsided to their former frequency, and were not increased by replacing the animals on the ground. In the fourth dog the pulsations 24 hours after division of the nerves were 140 on the floor, and instantly rose to 180 on the table. After waiting until they had again fallen to their former frequency, they were not increased by replacing it on the ground. In the sixth dog the pulsations were 140 the third day after the section of the nerves, when the animal was on the floor, and were raised to 160 by placing it on the table. In these experiments it was particularly observed, that the animals made no struggles in carrying them to and from the table, and, consequently, the increased excitation of the heart must have arisen from the mental emotion of terror. In the seventh dog this was conjoined with violent struggles. The pulsations, eight hours and a half after the operation, were 130; when placed on the table, and made to struggle, the pulsations as far as could be made out were about 220; when he had been subjected to pain, and had struggled more violently, they became so frequent that they could not be accurately reckoned, but were at least 260 in the minute. A large tube had been previously introduced into the trachea in this last animal. These experiments are, we conceive, sufficient to prove that, after section of the vagi, the pulsations of the heart may not only be quickened by muscular exertion, but also by mental emotions. Though in all probability the vagi are the usual channels through which mental emotions affect the heart, yet it appears from these experiments that this may also take place through the medium of the ganglionic system of nerves.

"*Pulmonary Branches of the Vagus.*—In my former paper I gave the results of several experiments from which, in opposition to the observations of Magendie, Wilson Philip, and Swan, I concluded 'that lesion of one of the pneumogastrics does not necessarily or even generally induce disease of the lung of that side.' Since that time I have carefully examined the lungs of two dogs and a cat killed some time after a portion of one vagus had been removed. One dog lived two months, the other nine days, and the cat three weeks. No morbid change could be detected in the lungs."

Then on page 193: "To show that others have also sometimes observed great insensibility of the mucous membrane of the trachea, even when the vagi were entire and uninjured, I have only to refer to the works of Haller. He there relates several experiments upon different species of quadrupeds, two cats, a she goat, a rabbit, a lamb, a he goat and a sheep, in which the trachea was opened, and various irritating substances, such as oil of vitrol, butter of antimony, and fumes of sulphur were introduced into the air passages without exciting cough. Some of the animals gave indications of suffering, and breathed forcibly."

Then on page 197 (this was his own experiment). "The animal the subject of the 14th experiment coughed so incessantly during the three last days of its life that I could not reckon the respirations until after many trials, and even then imperfectly."

Then on page 87: "It is unnecessary to state how much these experiments are at variance with the opinion of Sir C. Bell, that the function of this nerve is to associate the movements of the tongue and pharynx with the muscles of respiration in the instinctive movements of deglutition," and that is the way they go on.

Then on page 88: "We have lastly to inquire in what manner the section of the glosso-pharyngeal nerve affects the sense of taste. My observations on this head are in perfect accordance with those of Dr. Alcock. Dr. Alison had an opportunity of witnessing the persistence of the sense of taste in one of the dogs, after a portion of the trunk of the nerve on both sides had been removed, and Dr. Sharpey was perfectly satisfied that the animal, the subject of the sixth experiment, was sufficiently sensible of disagreeable impressions upon this sense; and though in the case witnessed by Dr. Alison a few pharyngeal filaments, and in that witnessed by Dr. Sharpey one pharyngeal twig on one side were found to have been left uncut, yet it was obvious that the rejected morsel sprinkled with coloquintida was fully recognised before it passed beyond the anterior part of the mouth. I need not add that the lingual portion of the nerve was fully divided in both of these cases. The remark, however, was repeatedly made (and it is of importance as explaining the error of Panizza on this point), that if animal food was offered and the dog very hungry he would eat the morsel containing the coloquintida rather than lose it; though he refused it if he saw any prospect of procuring another free from the bitter. The subject of the first experiment in which, as was stated, the glosso-pharyngeal was cut on one side only even ate readily several pieces of bread dipped in a strong solution of gentian root." (Othello, I think, says, "As bitter as coloquintida." I suppose they picked out the bitterest thing they could find). "Lest any doubt may arise that the presence of a few pharyngeal branches could have influenced the sense of taste, I may adduce the subject of the fourteenth experiment to prove that when the nerve is divided before it has given off a single filament, still the animal retains a sufficiently acute perception of disagreeable savours. I have fed that dog with morsels of animal food from my hand, and after he had taken several morsels in this way, which he readily swallowed, I then presented a morsel similar in size to the others, and with the coloquintida concealed in a way that he could not see it, but no sooner was it taken into the mouth than it was rejected with evident symptoms of disgust. This was repeated more than once."

Then on page 90 this passage occurs: "I endeavoured to ascertain the state of the sensibility, and of the sense of taste in that portion of the tongue where this nerve is ramified, after the trunk had been divided on both sides; but from the restlessness and struggles of the animals I was unable to arrive at any satisfactory results." All that torture was thrown away even according to his own account. He had knocked down Bell I suppose, and some one will knock him down if they have not done it already.

Then I find this at page 163: "*Pneumogastric Nerves.*—I have again had ample opportunities of confirming the statement made in my former communication drawn from experiments upon dogs, rabbits, cats, and calves, that the pinching, cutting, and even the stretching of the vagi nerves when exposed in the neck, are in by far the greater

Mr. G. R. Jesse.

6 Nov. 1875

majority of cases attended by indications of severe suffering. In opposition to the opinion expressed by Dr. M. Hall and Mr. Broughton, that the nervus vagus is not a nerve of sensation, I adduced the authority of Haller, Brunn, Dumas, and Dupuy. If additional evidence be thought necessary I may also add to those the names of Molinelli, Mayo, Magendie, and Brachet. In the first and fifth experiments upon the vagus, related by Molinelli, it is expressly mentioned that the animals (dogs) gave indications of suffering in tying these nerves with a ligature. Mr. Mayo says that 'asses, cats, and dogs almost invariably express great pain when this nerve, yet 'entire, is pinched with the forceps, and after its 'division equal suffering appears to result from 'pinching the part connected with the brain.' Magendie, in pointing out to his pupils an experiment where the nerve was stretched and cut without exciting pain, remarked 'In certain cases, on the 'contrary, the nervus vagus appears to possess the 'most exquisite sensibility; for it is scarcely touched 'without exciting immediately cries and convulsive 'motions.' (That does not look as if they felt no more than a piano-forte, as Dr. Crichton Browne stated of Dr. Ferrier's experiments.) "Brachet in one experiment irritated the upper end of the cut vagus with the view of subjecting the animal to suffering, and with success. I attempted to give an explanation of the source of fallacy which had misled Dr. M. Hall and Mr. Broughton in their very limited number of experiments; but I am now convinced that there is another circumstance more likely to lead to such errors than the one I mentioned, and that is the very different degrees of sensibility possessed by different animals, even of the same species."

Then at page 64 there is this: "*Part First, Glosso-Pharyngeal Nerve.*—The experiments on this nerve were all performed upon dogs, and were twenty-seven in number. Seventeen of these were for the purpose of ascertaining if it should be considered a nerve both of sensation and motion; and what are the effects of its section upon the associated movement of deglutition and on the sense of taste. The other ten were performed upon animals immediately after they had been deprived of sensation."

Now if you will allow me to make the remark, I will read the two next short sentences out of justice to this Dr. Reid. So far as my experience has gone it is almost, if not quite, the only instance in which I have found a thorough physiologist (when I say "physiologist," I use the word in the sense of an experimenter upon animals, putting them to torture for so called scientific purposes) with any shade at all of mercy; and perhaps that bore fruit in regard to his last hours. On page 112, I find this "I was anxious to ascertain whether irritation of these nerves would produce closure of the glottis by a reflex action. As the experiment is one in which it is difficult to arrive at accurate conclusions without inflicting much pain, I did not persevere in the attempt." Then on page 221, "The muscular movements of the stomach were, however, in all of these animals so indistinctly marked that I could obtain no satisfactory results; and as the experiment was a cruel one I did not persevere in it."

I will now read from Lockhart's Life of Scott, Volume IX., page 297, chapter 77, Letter to Miss Edgeworth, 4th of February 1829. I must hark back in regard to this. I am going to read this to strengthen what I stated in regard to the demoralizing effect which torturing animals produces upon those who inflict that torture; and I am now going to bring forward the evidence of no less a man than Sir Walter Scott, not only a man, as everybody knows, of high intellectual calibre, but nobody could call him unduly sensitive or enthusiastic, for a more daring and intrepid man has seldom lived. "I am no great . . . . learned carcase-butcher.'

I shall next quote from "Personal Recollections from Early Life to Old Age of Mary Somerville," &c. "London, John Murray, Albemarle Street, 1874." I do not think I can bring forward any authority more deserving of respect. She was so appreciated by scientific men that her bust is placed in the rooms of the Royal Society, an honour which I think was never before conferred upon any lady, at least I believe so; it is many years since I saw it. At page 192 you will find this: "The Marquise de La Place . . . . kindly nature abhorred."

At page 306 there is this passage: "A German professor . . . . not a little."

On page 348, this is towards the close of her life, she says, "The short time . . . . the lower animals."

The book from which I am now about to quote is, "Researches into the History of the British Dog," written by myself, and published in 1866. This is a quotation from Pope: "I cannot think . . . . use to us?' See Spence's Anecdotes, Singer's edition, page 203, and Pope's paper in the Guardian, on Animals, 21st May 1713."

5565*a*. (*Mr. Huxley.*) What is the title of the book from which you read that?—"Researches into the "history of the British dog." Published in 1866.

5565*b*. By whom is it written?—By myself.

I shall now quote from "Proceedings of the Royal Society, volume 22, number 151." This is in reference to the substance of what I read when I attended here on the previous occasion, in regard to Dr. Ferrier's experiments. "March 5th, 1874. Joseph Dalton Hooker, C.B., President, in the chair." The following paper was read:—"The Localization of Function in the Brain. By David Ferrier, M.A., M.D., M.R.C.P., &c. 1874. (Abstract.) The chief contents of this paper are the results of an experimental investigation tending to prove that there is a localization of function in special regions of the cerebral hemispheres. In a former paper published by the author in the 'West Riding Lunatic Asylum Medical Reports,' Vol. III. 1873, the results were given of experiments on rabbits, cats, and dogs, made specially for the purpose of testing the theory of Hughlings Jackson, that localized and unilateral epilepsies are caused by irritation or 'discharging lesions' of grey matter of the hemispheres in the region of the corpus striatum. Besides confirming Hughlins Jackson's views, the author's researches indicated an exact localization in the hemispheres of centres or regions, for the carrying out of simple and complex muscular movements of a definite character, and described by him as of a purposive or expressional nature. Facts were also recorded tending to show that other regions of the brain were connected with sensory perception, but no localization was definitely arrived at. Among the experiments now related are some in further confirmation and extension of those already made on cats, dogs, and rabbits, as well as a new series of experiments on other vertebrates. In particular, numerous experiments on monkeys are described, for the purpose of which the author received a grant of money from the Council of the Royal Society. In addition, the results of experiments on jackals, guinea-pigs, rats, pigeons, frogs, toads, and fishes are narrated. The method of investigation" (I wish to draw particular attention to this passage, as a good deal has been said about the animals being under anæsthetics,) "consists in the application of the stimulus of an induced current of electricity directly to the surface of the brain in animals rendered only partially insensible during the process of exploration, complete anæsthesia annihilating all reaction. It is supplemented by the method of localized destructive lesions of the hemispheres." That was the point that we wished to make about that.

I shall now quote from page 378, of "Proceedings of the Royal Society, volume 23, number 161, April 29th, 1875. The Duke of Devonshire, K.G., Vice-President, in the chair. The Right Hon. W. E. Forster and the Right Hon. Russell Gurney, were admitted into the Society." And at page 409, I find "Experiments on the Brain of Monkeys, No. 1, by David Ferrier, M.A., M.D., M.R.C.P., Professor of Forensic Medicine, King's College, London. Com-

Mr. G. R. Jesse.

6 Nov. 1875.

municated by Dr. J. B. Sanderson, F.R.S." The facts recorded in this paper are the results obtained by electrical stimulation of the brain of monkeys, after the method described by the author in the West Riding Lunatic Asylum Medical Reports, volume III., 1873. They formed part of a paper "On the localization of function in the brain," read before the Royal Society on March 5th, 1874. (See Proceedings, vol 22, p. 229.) This memoir also contained the results of other experiments on the brain of monkeys chiefly relating to the effects of localized lesions of several parts of the hemispheres, with a view to determine the significance, as regards sensation and motion, of the phenomena caused by electrical irritation. These experiments are not here recorded, but are reserved for comparison with the results of a more extended reinvestigation of a similar nature, on which the author has been for some time engaged, and which will shortly be laid before the Society. In order to avoid unnecessary detail, and in order to place the results together for the purposes of comparison, the animals experimented on are described, the dates of experiment given, and numbers assigned to them, so that they may all be brought into relation with each other:—"Experiments on monkeys (Macaques), No. 1, left hemisphere, June 14, 1873. No. 2, right hemisphere, June 18, 1873," and so on at different dates, 13 of them.

Then at pages 419 and 420, I read: "X. A similar result. In this case, after several other parts had been under exploration, excitation of this region gave rise to a species of epileptic fit, beginning in the left angle of the mouth, next proceeding to the left arm and hand, and lastly affecting the left leg and tail. The spasms next attacked the right angle of the mouth, the right arm, and the right leg in succession. The fit lasted several minutes. The pupils were not dilated, nor did the animal apparently lose consciousness completely."

Then on page 423, speaking of experiment 13: "The result in this case was also negative. To test this matter more fully, another monkey, not among those already numbered, was experimented on on December 10."

On page 424, there is this paragraph: "In a later experiment (December 2), on another monkey it was found that stimulation of the frontal part of the brain caused the eyes to move to the opposite side. This was found to be the case with irritation of both right and left hemispheres. The eyelids were not always opened, however, nor was dilatation of the pupils observed. Sometimes also the eyes moved upwards, instead of to the opposite side, &c."

On page 425, there is this passage. "IX. Both eyes directed upwards and to the left. Pupils contracted. In this animal," (I beg particular attention to this,) "which was allowed to remain quite conscious during stimulation, an experiment was made as to vision by holding before it a teaspoonful of milk, which it was eager to seize. In its attempt this point was stimulated, with the effect of causing confusion of vision and some difficulty in reaching the milk."

At the bottom of page 426, this paragraph occurs: "Nothing very definite was arrived at. In some the results were altogether negative; in others the following phenomena were noted, perhaps not altogether satisfactory as to their nature."

Then I find on page 428 this: "Occipital lobes (superior and middle convolutions). These were experimented on in 1, 3, 5, 7, 8, 9, 10, 11, and 12; also in another not numbered, on November 21." "In the case of 10, it was observed that stimulation of the inferior occipital convolution towards its inner aspect caused uneasy movements in the hind legs and tail, the head being turned to the left (opposite side) and backwards. Occasionally also a plaintive cry, as if from annoyance, was uttered. On cessation of the irritation the animal subsided into its dozing state."

On page 429, there is this passage: "*Corpora quadrigemina.* The ganglia were subjected to experimentation in the following seven cases, viz., V, VI, VIII, IX, X, XII, XIII, with the results:—V. In this case the exploration was not sufficiently definite, as the exact position of the electrodes was not observed, and death occurred before a more careful exploration could be made. The application of the electrodes to the ganglia on the left side (position as to the testes or nates not ascertained) caused the animal to utter various barking, howling, or screaming sounds of an incongruous character. The head was drawn back and to the right, and the right angle of the mouth was strongly retracted, while the stimulation was kept up. Tho tail was raised and the limbs were thrown into contortions, but nothing further was ascertained, as the animal died from hæmorrhage. VI. In this case irritation of the right anterior tubercle (nates) caused intense dilation of both pupils (especially beginning in the left), elevation of the eyebrows, and turning of the eyeballs upwards and to the left, at the same time that the head was turned in the same direction, with an intensely pathetic expression. Momentary application of the electrodes to the posterior tubercles (testes) caused the animal to bark loudly, the sound passing with longer stimulation into every conceivable variation of howling and screaming. Continuous application of the electrodes for several seconds caused ultimately firm clenching of the jaws, retraction of the angles of the mouth (particularly the left), elevation of the eyebrows, and retraction of the ears. The pupils were dilated, eyes widely open, and the head thrown back. The tail became elevated, the limbs, after contortions of various kinds, became rigidly drawn back, the arms drawn back and flexed at the elbows, and closely approximated to the sides. A complete state of opisthotonus was induced. The dilatation of the pupils occurred on irritation of both nates and testes; the screaming, &c., only on irritation of the testes. VIII. The results in this case were essentially the same in VI. as regards the dilatation of the pupils, howling, and rigidity of the limbs, &c. IX. As before, stimulation of the anterior tubercle on the right side caused elevation of the eyebrows, dilatation of the pupils, and turning up of the eyes to the left. Irritation of the ganglia for some time caused a condition of opisthotonus, and the phenomena described under VI. Irritation of the testes caused utterance of every variety of barking and howling, ultimately trismus and general opisthotonus. X. Exactly as in IX. XII. As before, irritation of the testes caused barking and howling. When the animal was nearly dead irritation of the testes caused only powerful retraction of the angles of the mouth, so as to show the firmly clenched teeth. XIII. In this case the results as to the nates and testes were in every respect similar to those already detailed in the former cases." Then he goes on to say at the bottom "On this point, however, further experiments are necessary."

Now I will quote from "Proceedings of the Royal Society, volume 23, No. 162, May 13th, 1875. Dr. J. Burdon-Sanderson, Vice-President, in the chair. The Croonian Lecture, 'Experiments on the Brain of Monkeys' (second series), was delivered by David Ferrier, M.A., M.D., Professor of Forensic Medicine, King's College. Communicated by Dr. Sanderson, V.P.R.S. Received April 27, 1875. The following is an abstract." And it says on page 432, "No. 5. Destruction of the hippocampus major and hippocampal convolution abolishes the sense of touch on the opposite side of the body." No. 9. "Ablation of the occipital lobes produces no effect on the special senses or on the powers of voluntary motion, but is followed by a state of depression and refusal of food, not to be accounted for by mere constitutional disturbance consequent on the operation. The function of these lobes is regarded as still obscure, but considered to be in some measure related to the systematic sensations. Their destruction does not abolish the sexual appetite." I wonder how he arrived at that! He made some experiments no doubt in that way after the style I suppose of Dr. Brachet described by Dr. Elliotson; at least it seems probable.

Mr. G. R. Jesse.

6 Nov. 1875.

"10. After removal both of the frontal and occipital lobes, an animal still retains its faculties of special sense and the powers of voluntary motion." Then I would refer you to "Proceedings of the Royal Society, volume 23, No. 159."

Then I will next quote from the Saint Bartholomew's Hospital Reports, volume 9, London, Longmans, Green, and Co., 1873. Article 12, page 161, "On the changes of the liver which follow ligature of the bile ducts, by J. Wickham Legg, M.D." On page 162 he says this: "During the past winter I have made several observations upon the changes which follow ligature of the bile ducts in animals. The animals used were cats; these seemed to survive the operation better than dogs. Most observers find that dogs live only five to ten days after," long enough in that misery.

Then on page 163 he goes on to say: "All the operations recorded in this paper were done in the pharmacological laboratory of my friend and colleague Dr. Brunton, I am therefore glad of this opportunity to express my most sincere thanks to him for his courtesy on this, as on many other occasions. Had I to repeat these experiments I should choose only young, not fully grown animals, and a warm time of year. Though the cats were kept in a warm place, and the January of this year was mild, yet three of them were found dead one morning after a slight frost in the night."

Then on page 175, Experiment XVI, that is on 16 cats I believe. (I do not read the others because they would not strengthen our cause and would only take up time, and one sack of wheat out of a hundred of course is sufficient to show the character of the other sacks.) "June 27. Black and white cat, well "nourished, full grown. Bile duct tied double and "piece cut out. July 3," (that will be six days afterwards,) as the cat was now very weak and seemed about to die, it was determined to make the diabetic puncture. The cat was therefore laid prone, a cut made through the skin over the occipital protuberance, and the chisel applied immediately underneath this. After dividing the occipital bone the chisel was passed in a direction downwards and forwards so as to cut the line made by joining the two auditory meatus. The chisel was pushed on until it met with the basilar bone, and was then withdrawn. Operation was over at 12.30. Before the operation the cat had languidly taken a little milk; urine passed during the operation; though highly jaundiced, gave no reaction with Trommer's test. At 2.15 urine pressed out of the bladder gave no reaction with Trommer's test. July 4, cat still alive; urine gave no reaction with Trommer's or Moore's test. July 7, the cat died in the night between July 5 and 6. Examined today at two o'clock. Much more peritonitis than in any other of the experiments. The upper and under surfaces of the liver covered with a layer of exudation; the fluid in belly turbid. Complete obstruction of the gall ducts. No microscopical examination of the liver. *Analysis of the foregoing cases.* As regards time of death: 16 cats had their bile ducts tied; three of these died from prolapse of the bowels, two on the fifth, and one on the seventh day after the operation. Another cat had the diabetic puncture done on the sixth day after the operation, and died probably on the ninth day. So in twelve only was the natural progress of events interfered with. Out of these twelve, two died on the third day, two on the fourth, and one on the eighth, tenth, fourteenth, sixteenth, eighteenth (but in this case only the left hepatic duct was tied), and twentieth days respectively. Two cats were killed on the twenty-seventh and twenty-ninth days; the bile had found again a natural passage to the intestines. This curious result was noticed by Brodie, one of the earliest to make the experiment of ligature of the bile ducts. (Brodie, 'Quarterly Journal of Science, &c.' London, 1823, vol. xiv., p. 344.)"

Then on page 177: "The cause of death in these creatures is obscure. Blondlot, and many other observers, attribute it to peritonitis. Blondlot gives a distinct cause. He says that the ligature eats through the bile duct; the bile is thus poured into the peritoneum (Blondlot, '*Traité analyt. de la Digestion.*' Paris, 1843, p. 174.) In my own cases, I did not notice this in one instance, although in all cases the bile ducts were carefully dissected out. The ligature was around the duct in every case. Peritonitis can scarcely be set down as a valid cause. In all, the marks of peritonitis were so slight and so limited to the part between the under surface of the liver and the duodenum, that it was impossible to attribute the fatal result to this local disturbance. In none of my cases too was the suppuration from the wound at all considerable. It had usually ceased at the end of the first week."

Then in the next paragraph he says: "Leyden seems to think that it is the addition of the jaundice to the peritonitis which kills the animals. Experiment XV. would seem to discredit this explanation. Here only one branch of the hepatic duct was tied; yet the cat died on the eighteenth day, although no jaundice had been set up at the time of death. Again, dogs, in whom biliary fistulæ have been set up and again closed, live for months, notwithstanding an intense jaundice. I should be far more inclined to attribute the cause of death to the changes which take place in the liver." I do not think I need go on with that; there is anough to show that he disagrees with him on that point.

I will next quote from the British Medical Journal, October 23, 1875. Experiments on the Biliary Secretion of the Dog, by William Rutherford, M.D., F.R.S.E., Professor of the Institutes of Medicine in the University of Edinburgh, and M. Vignol ———. I do not wish to read much out of this; I bring it forward partly to show that these painful experiments upon animals are still carried on; at all events this appears to be incomplete, and it is of the date I have just read. So that it shows that these men do not care to wait for any opinion of the Royal Commission; but they are going on on their part, and in a way which we esteem contrary to the Act of Victoria.

"Two years ago, Röhrig," and so on, "performed a number of experiments on the effect of various substances on the biliary secretion," and so on. "Method of experiment. All our experiments were performed on dogs that had in nearly every instance fasted about eighteen hours. After paralysing the animal with curara, and establishing artificial respiration, we opened the abdomen in the linea alba, and tied a glass cannula in the common bile duct, near its junction with the duodenum. To the end of the cannula which projected from the abdomen, we attached a short india-rubber tube, and to the end of this again a short tube of glass, drawn to a narrow aperture, so that the bile might drop from it. The gall-bladder was then compressed, in order to fill the whole tubing with bile and the cystic duct was clamped to prevent the return of the bile to the gall-bladder, and so compel all the bile secreted by the liver to flow through the cannula. The wound in the abdominal wall was then carefully closed, and in all our later experiments the animal was thoroughly covered with cotton wool, in order to quickly restore it to its normal temperature."

Then page 2: "As is well known, curara is of great value in such experiments, for by paralysing voluntary movement, it prevents the irregular outflow of the bile, which certainly follows irregular contraction of the abdominal muscles; and if care be taken to give doses just sufficient to produce this paralysis, the biliary secretion is not apparently affected; but if too much be given, the heart is rendered weak and irregular, and the secretion of the bile diminished."

Then I go on to page 3: "It therefore appears that in the progress of the experiment the composition of the bile remained almost precisely the same. This is remarkable, seeing that the animal had been deprived of water for so long a time" (there he tortured the animal, or something like it) "and, moreover, seeing that the entrance of the bile into the

Mr. G. R. Jesse.

6 Nov. 1875.

intestine had been cut off. It should be mentioned that in taking the bile secreted near the beginning of such experiments for analysis, we were always careful to eliminate that which had been expressed from the gall-bladder into the cannula."

Then there is additional matter on the same subject in the British Medical Journal, October 30, 1875. I have a pencil memorandum from the gentleman who sent me this. He says, "Among the allotments of the Scientific Grants Committee of the British Medical Association is Professor Rutherford's Researches on Biliary Secretion, 25*l*." Then at page 7, "Experiment 15. Dog weighing 9·5 kilogrammes. In this experiment it was proposed to test the effect of aloes on the liver when well nigh exhausted; accordingly at the sixth hour of an experiment on a dog that had fasted the usual period of 18 hours, twenty grains extract of Socotrine aloes in 5 c.c. of water were injected into the duodenum (*a*, figure 15), and this dose was repeated in half an hour. The secretion of bile was increased, but the effect was not very marked; nevertheless, the result is noteworthy, seeing that in this case there was a great secretion of bile during the first four hours of the experiment (fig 15)."

Then the last experiment which is recorded here, but the paper does not seem to be finished, is experiment 16, on injecting rhubarb.

5566. If there are any further passages in published works to which you wish to refer us, will you, if you please, simply give us the references to them now, and then proceed to say anything that you have to say?—I would refer to the Hand Book for the Physiological Laboratory, edited by Dr. Burdon-Sanderson, 1873, and the pages to which I would call attention are pages 210, 212 (rabbit, &c.), 238 (spinal cord), 245, 308, 403 (dogs and cats recovered from chloroform), 404 (frogs), 409 (frogs), and 417 (pigeons). Then I would refer to "An Inquiry into the Process of Nature in Repairing Injuries of the Intestines, illustrating the treatment of penetrating wounds and strangulated hernia, by Benjamin Travers, Demonstrator of Anatomy at Guy's Hospital, &c. London, 1812." We put in that book as containing cruel experiments to animals generally. And then, "The Wrongs of the Animal World; to which is subjoined the speech of Lord Erskine on the same subject; by David Mushet, Esq., London, 1839." The pages to which I would refer are pages 191, 228, 229, and 201 and 202. In regard to the fact that these so-called experiments are perpetrated at the present day, and to a very considerable extent, though some people deny it, we wish to refer to what was done at Norwich, in the case of that Frenchman Dr. Magnan. It was done publicly, and there was a prosecution, or rather an attempted prosecution; he somehow or other managed to escape. There was a miscarriage of justice there, as we should say, and he was not apprehended. I do not mean that it failed through anything wrong in regard to the magistracy, but simply that he was not brought before them. Then I would refer to "The Physiological Pathology and Treatment of Asphyxia, by James Phillips Kay, M.D., formerly President of the Royal Medical Society, Edinburgh; London, Longman, 1834." That book we put in generally in the same manner. Then the next book is "Physiological Researches, by Sir Benjamin C. Brodie, Bart., London, Longman, 1851." We put that in generally. There is something which I should now like to refer to, the opinion of Alexander Chalmers in regard to the Abbe Spallanzani; I think it is in the Biographical Dictionary.

5567. You must not rely on our having printed in the Blue Book everything which you have read to us or to which you have referred us in published books; the Commissioners will exercise their discretion with regard to that. I will now ask you, have you said all that you wish to say to the Commission?—No.

5568. What is the nature of that which you have further to address to it?—It is to show the cruelty and inutility of these practices.

5569. You have put in the references to the various books that you wish us to consider?—As I have gone on I have done so.

5570. You have exhausted that portion of the subject?—I do not know that I have quite.

5571. Do you know that you have not?—I could not answer decidedly at the present moment; I should like to refer.

5572. Then you mean that you are not able in the course of this present examination to conclude your evidence in that respect?—I think not quite.

5573. Have you any observations that you are desirous of offering before to-day's examination closes?—No. I would reserve them till another day. I am tired now; my health is not strong, and I am not accustomed to read like this.

5574. At any rate to-day you are not prepared to address any further observations to the Commission?—If it was a matter of necessity, now or never, I should endeavour to do something.

5575. Then we will ask you to proceed now?—Could you not take me on Monday? I make that request.

5676. The arrangements of the Commission do not enable us to meet on Monday?—Or on any future day?

5577. If you have any observations that you wish to address to us now, we wish you to proceed wth them?—I have given my reasons for not doing so. I could hardly do justice I think to the Society and my clients if I went on now.

The witness withdrew.

Adjourned.

Saturday, 11th December 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. Lord WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.

THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq., Secretary.

Mr. W. B. Carpenter, C.B., M.D.

11 Dec. 1875.

MR. WILLIAM BENJAMIN CARPENTER, C.B., M.D., called in and examined.

5578. (*Chairman.*) You are Registrar of the London University?—Yes.

5579. I think you were formerly Lecturer on Physiology at the Bristol Medical School, and afterwards at the medical school of the London Hospital?—Yes.

5580. And I need not ask you if you are the author of the well-known book upon the Principles of Human Physiology, and of a book upon the Principles of General and Comparative Physiology?—Yes.

5581. And I believe of several articles in the Cyclopædia of Anatomy and Physiology?—Yes.

Mr. W. B. Carpenter, C.B., M.D.

11 Dec. 1875.

5582. I doubt not therefore your attention has been directed to the subject into which we are instructed to inquire?—Yes. I have taken from a very early period a great interest in the progress of experimental physiology.

5583. Are you of opinion that as it is conducted in this country, to which we limit our inquiry, it is, generally speaking, conducted by persons of a sentiment of humanity towards animals?—I know nothing to the contrary.

5584. You believe that to be so?—I believe it to be so.

5585. If it should be at the present moment rapidly extending, would that in your opinion be a reason why some general regulation should be arrived at for its government?—If any such regulations could be efficiently applied. I have a very strong objection to any legislation that cannot be thoroughly carried out,—that can be evaded.

5586. You think that any law which was adopted for the purpose should be one which it was possible to carry into effect, and which it was intended really to carry into effect?—Yes.

5587. And if such a law as that could be adopted without interfering with the progress of physiological science, are we to understand that it would have your approval?—Quite so.

5588. Have you considered at all the details of the various measures that have been proposed?—I cannot say that I have. I merely know their general idea of licensing places and persons, or places or persons.

5589. You are aware that some of the greatest names in science are associated with a Bill which was introduced into the House of Commons in the last session by Dr. Playfair?—Yes.

5590. If you have not yourself considered the details of that Bill I will not examine you upon the details, but will only generally ask you whether in your opinion the names to which I have referred are names that would carry generally the confidence of persons in medical science?—I am not sure that they have considered all the points and difficulties which would naturally arise.

5591. But I ask you whether the names are the names of those persons who are most likely to carry the confidence of the scientific world in this country?—So far as I recollect them they were, certainly.

5592. I understand that you have not yourself considered the details of that Bill?—No.

5593. Therefore we must only ask you hypothetically. If they have considered the details of it you would attach great weight, I presume, to their opinion?—Not altogether to the exclusion of my forming an independent opinion.

5594. But I presume that you would form that independent opinion rather after having considered the details of the measure than before, would you not?—Certainly; but as far as I understood the details of that measure (I cannot say that I carefully studied them, because I saw very soon that the Bill was withdrawn) there would be to my apprehension very grave difficulties in working it effectually. For instance, I could not see how it could exclude or take cognisance of the performance of physiological experiments in private houses; or how it was possible to draw any definite line between the performance of an experiment that no sensible man would object to, and the performance of a cruel and painful experiment. There is a gradation from one to the other; and my great difficulty in the consideration of this subject has been, to find how any definition can possibly be framed to apply to the class of experiments which it is desired to restrict, without interfering with the class of experiments which I think are perfectly legitimate without restriction,—experiments which any man ought to be able to perform in his own house without interference from legislation.

5595. Then, viewing it rather in a general way, you rather despair of it, than come down to the particulars of these special measures and say that they fail in doing it?—My position is this, that in view of the gradation of which I have just spoken,—between, for instance, putting a frog under the microscope to look at its circulation, which I should say no one ought to interfere with any man showing to his children in his own house, and what are properly called physiological experiments,—I do not see, and I never could see, where and how to draw the line.

5596. Then, as far as it has yet occurred to you, it is impossible that a law should be passed which could accomplish the object which we have in view?—A law that should be really effectual without unduly interfering with the liberty of the subject.

5597. (*Lord Winmarleigh.*) When you state that there would be a difficulty in reaching the practice in private houses, does not that observation apply to a number of other things that are under legislation at the present moment?—I have contrasted it in my own mind with the Anatomy Act. The Anatomy Act does not prevent anyone from dissecting a dog or a cat in his own house; it simply applies to the dissection of the Human body as a whole; and no person may legally perform dissection of a human body in any other place than in a licensed building and under authorities who have a license. But every medical man does perform dissections of parts of human bodies in his own house; every medical man who goes to a post mortem examination, and finds something of interest to him, brings it home to study more carefully. That is a case in which it seems to me that a broad general line may be drawn; because there is a pretty clear common sense distinction between the two things, the regular practice of dissection for the education of students in a medical school, and the dissection of small portions of a body which a medical man may bring home to examine more carefully. The Inspector of Anatomy, who looks strictly after the one, would never dream of interfering with the other. But I cannot see how such a line can be drawn with regard to physiological experimentation.

5598. I think you misapprehend the object of my question. You stated that one of your objections to legislation was that you could not reach this practice in private houses. Now I will take a subject in strict connection with the one which we are investigating; I will take the subject of cock-fighting, for instance. It is contrary to law; Parliament is not prevented from legislating very usefully against cock-fighting, by the idea that you could not reach it in private houses; it is illegal in private houses, and we trust to the feelings of persons that it will not be practised in private houses when it is illegal. Does not that remove the difficulty that you have expressed with regard to legislation reaching private houses?—I think not, for I do not see how it could be possible for legislation to reach it in a private house. Cock-fighting is a thing which is to a certain degree notorious; the cocks cannot be brought there without the knowledge of others, and their noise is heard. Allow me to give a nearer parallel, namely, the action of the Maine Law, which I have studied and thought of a great deal, in the countries where it prevails. I know perfectly well that it is impossible by any Maine Law to prevent drinking in private houses.

5599. But does it not check it?—No, I believe not; I believe rather the reverse.

5600. I will return to cock-fighting. It is a known fact that there are instances still where cock-fighting is carried on by stealth in private houses; but it has been very much checked through the country, has it not, by the legislation which has taken place on the matter?—I presume that it has, but I trust very much more to a healthy public sentiment on the subject.

5601. (*Mr. Erichsen.*) You have as yet expressed no opinion as to the importance of vivisectional experiments upon animals as a means of scientific investigation?—I have no hesitation in saying that it is of the most fundamental and essential importance, and that it is impossible that physiology can be studied without it; and that if anyone will take the trouble to go over the history of physiology for the last half

Mr. W. B. Carpenter, C.B., M.D.

11 Dec. 1875.

century, for example, to go no further back than the researches of Sir Charles Bell, he will see that the whole fabric of our accurate knowledge of physiology depends upon experiment. And having been asked that question, I would take leave to make a statement in regard to an assertion which has been made, that Sir Charles Bell himself regretted that he had made physiological experiments, and that he declared that he had done so merely to satisfy others, and that he could have arrived at all at which he did arrive by anatomy only. Whether Sir Charles Bell made that statement, or not, I do not know; but it is perfectly notorious to all those who have studied the history of his discoveries, that he was led into his early mistakes, which had to be corrected by other physiologists, simply by trusting too much to anatomy; he formed certain ideas on the basis of anatomical research, which ideas had to be corrected by experiments made by himself and by others. It is an entirely erroneous notion to suppose that Anatomy can lead by itself to any certain Physiological deduction, without putting that deduction to the test of experiment.

5602. And with regard to the importance of physiological experiments as a means of demonstration to students, what is your opinion?—I think that a very clear line may be drawn in regard to demonstrations. I think that no experiments involving animal suffering need be made for the purpose of demonstration of physiological facts and doctrines already perfectly well ascertained. My own conviction has long been that that is not only unnecessary, but that it is morally injurious. But on the other hand there are a very large number of physiological experiments which may be made, and ought to be made, in my opinion, in the presence and for the instruction of medical students, that can be made without animal suffering. I think we have as much right to destroy the life of an animal, —to cut off the head of a turtle, for example, and to exhibit the great phenomena of reflex action upon its dead body, as we have to kill it for food.

5603. (*Mr. Hutton.*) Would you put any limit on the painful character of the experiments to be made for scientific purposes, or would you justify the infliction of any amount of pain for a sufficient scientific purpose?—I should certainly justify it for a well considered purpose, if that pain could not be avoided. There are certain cases in which the use of anæsthetics would neutralise the result; and I think that the history of science shows that some of those experiments have been of very great importance. The whole series of experiments made up to the time of the use of anæsthetics, by Sir Charles Bell, Dr. Marshall Hall, Dr. Waller, and others, were excessively painful experiments; but I should hold them fully justified in making those experiments. I witnessed a large series of experiments by my friend Dr. John Reid, in which a considerable number of animals were operated on at once; and the very valuable results which he worked out, were worked out entirely through his having used several animals, and not being satisfied with experiments on one animal. I may give this as an illustration:—At the time when Dr. Reid began his experiments, the doctrine was that the division of the *par vagum*, the eighth pair of nerves, destroyed digestive power. This was a very important physiological conclusion, but Dr. Reid had reason to suspect its correctness; and he found that it depended upon this, that the immediate effect was always to suspend the digestive power, that is, to destroy it for the time; but by making the experiment upon several animals, he found that while some of them sank under it, others survived; and in those that survived it, the digestive power returned without any reunion of the nerve. Now the establishment of that fact was one of fundamental importance in physiology, because it showed what is the degree of control which a nerve has over a secretion.

5604. My question was rather whether, quite admitting the scientific value of the experiment, you would scruple to inflict any amount of protracted agony, supposing that were necessary for the purpose of a good scientific result; whether in fact on moral considerations you would put any limit on the amount of agony to be inflicted?—I do not see where you are to draw the line. A humane man will shrink, no doubt, as Bell did in the first instance, from inflicting animal suffering; and it will be a question in his mind between the probable benefit to be derived and the value of the result. Now I may give this illustration. Dr. Brown-Séquard, who is one of the most humane men I know, has inflicted more animal suffering, probably, than any man in his time, unless it be some of the recent German experimenters; but his labours have extended over thirty or thirty-five years, and he has worked out, as every physiologist knows, results of the very greatest importance, by means of experiments which were often protracted through long periods. One of the most valuable of these, in its practical bearing, was the section of the spinal cord. At the time when he took up his inquiry, it was the received doctrine in physiology that the division of the spinal cord in the back would necessarily destroy life. Now this had a very important bearing upon the treatment of patients who suffer from accidental injuries to the spine. Cases of that kind are very common in the London hospitals; cases where men fall from masts of ships and strike the back, and have complete paralysis of the lower limbs; and every surgeon knows that it is excessively difficult to keep such patients alive for any considerable length of time, and that nurses suppose that they must die, and will neglect them. Brown-Séquard desired to ascertain if there was any necessarily fatal result from that experiment. He performed this section of the spinal cord in a great number of animals of different kinds—frogs, rabbits, guinea-pigs, and birds; and the immediate result of course was to produce complete paralysis of the hinder limbs; but by the most careful and tender nursing of these animals, he was able to keep them alive, warding off from them the injurious influences which would have otherwise caused gangrene of the limbs and death; and in that manner, carrying on this nursing through months which must have been to a certain degree months of suffering to the animals, he established the position that the spinal cord may be completely restored and the power of the limbs completely regained. Now this complete restoration of the spinal cord is not only a physiological fact of the very greatest interest, but of the greatest practical value to Man; because it encourages all the attendants of a sufferer under these circumstances in doing exactly what Brown-Séquard did with his animals, namely, giving the most careful attention to all the minutiæ which should prevent, remove, and antagonise so far as possible the consequences of the injury, in the hope, which has been now realized over and over again, of complete recovery.

5605. (*Sir John Karslake.*) May I ask whether in those cases the section of the spine was done under anæsthetics?—These experiments were performed before the introduction of anæsthetics; but the section itself is a matter of comparatively small moment; it is the after suffering of the animals which is the most painful to a humane mind; to see these poor creatures going on week after week, and month after month, in an artificially induced paralysis.

5606. (*Mr. Forster.*) Are those experiments still being made?—I should consider it quite unnecessary to make them now.

5607. You do not know whether they are being made by Dr. Brown-Séquard?—I doubt whether they are, because they require so very much trouble. The constant watchful care of the animals which is necessary is a thing which no man, not a thorough enthusiast, as Brown-Séquard is, would have carried on.

5608. Do you know on how many animals he tried the experiment?—I should think 40 or 50 at least.

5609. Now was it at all necessary to try it on so many?—I think so quite, for the same reason that John Reid found it necessary. In order to establish the fact that survival may take place at all under such cir-

Mr. W. B. Carpenter, C.B., M.D.

11 Dec. 1875.

cumstances, it is important to experiment upon several; otherwise, as one will die and another will die, you may come to the conclusion that death is inevitable.

5610. But do you at all know out of those 40 or 50 how many survived?—I should think about half from his description of the experiment.

5611. Then why should it be necessary to try it on so many after having ascertained that several did survive; after having ascertained, for instance, that five did survive, why should it be necessary to try it on more?—It was important to experiment on several different kinds of animals; for instance, it might be said that a frog would survive, but that a warm-blooded animal would not.

5612. (*Chairman.*) What was the use of proving that a frog could survive such a painful experiment, if no reasonable deduction could be drawn from that fact with reference to man?—In such an experiment as that, there would be no reasonable deduction from the frog; but the deduction may be drawn much more reasonably from a rabbit or guinea-pig or bird.

5613. (*Mr. Forster.*) Then that would seem to make the sufferings of the frog useless, would it not? —To establish the fact of regeneration in the frog would be the first step. I think a frog would suffer very little; my belief is that frogs have extremely little perception of pain.

5614. (*Mr. Huxley.*) Is there any evidence that a frog would suffer at all after the spinal cord was divided, because the consequences that take place in the higher animals which give rise to pain do not take place in a frog, and after the first operation I presume there is no evidence of pain?—I do not think there is any evidence of pain.

5615. (*Mr. Hutton.*) I gather that you would deny that there is any limit on the suffering that ought to be inflicted for a well-conceived experiment?—If that experiment is one which, after careful consideration of the results which may be expected from it, is likely to lead in any decided degree to the discovery of physiological truth, whether or not the immediate application to the alleviation of human suffering is apparent. All science shows us that the results of scientific truths in benefit to mankind are very often long postponed. The discovery of chloroform, for example, is a very characteristic instance of that. Chloroform for many years was a mere scientific curiosity; it was a compound not supposed to have any relation to human welfare.

5616. I see an experiment narrated in your own work on physiology, as to which I should like to know whether you think it really was a desirable one to make. I find this stated: "The introduction of a "little boiling water threw the animal at once into a "kind of adynamic state, which was followed by death "in three or four hours; the mucous membrane of "the stomach was found red and swollen, whilst an "abundant exudation of blackish fluid had taken "place into the cavity of the organ." It is not one of your own experiments, but one of which you are there narrating the results. Now do you not think that that might have been argued as one of the most certain inferences from the well-known facts of human experience, and that it was quite an unnecessary experiment to make?—That which you have just read is probably taken from a late edition of my book.

5617. It is the seventh edition by Mr. Power, page 129?—It is not an experiment that I am acquainted with. I have so far given up the study of Human Physiology, that I have really not kept pace with the inquiries to which that experiment relates.

5618. (*Mr. Forster.*) Then this experiment was not published by you?—No. I would not give an opinion upon it without knowing the purpose of it.

5619. (*Mr. Hutton.*) It is published in your book, but not by you?—Not by me.

5620. It is not a thing on which you would wish to offer an opinion?—I should certainly not wish to offer an opinion unless I knew the object of the experiment, and the ideas under which the experiment was made. But I might take another illustration, the study of the effects of poisons upon animals, the corrosive poisons, for example. It is essential to the study of Toxicology, as relating to Man, that most painful experiments should be made upon animals.

5621. I was not in the least denying that, but simply asking this. You have expressed the opinion that experiments are not usually made which are needless, and I was putting the case of an experiment that I thought was needless. Now, I see in a paper which has been presented to the Commission various experiments on gluing animals together, that is to say, removing the skin from two different animals, and binding them closely together, so that a new membrane forms which is common to both, and they are then by careful treatment enabled to live until they grow together, in fact. Now should you regard that as an experiment which has the slightest scientific value, or which is justifiable morally? Clearly it must involve the greatest possible misery to the animals so artificially united?—I should be sorry to answer offhand in regard to such an experiment, unless I knew the objects which the experimenter had in view. It might be that he had conceived a plan which might be of considerable importance in surgery, bearing on the question of how far a large and obstinate ulcer, for example, might be cured by endeavouring to induce the union of its surface with the surface of another animal. Every surgeon knows that the treatment of these large ulcers is one of extreme difficulty, and that the plan has been employed in recent times of taking small bits of skin from another part of the same individual, and planting them, as it were, upon the ulcer. I think it possible that these experiments were intended to test the question, whether the skin of another animal might not be so employed, and whether a considerable amount of human suffering might not be saved by transplanting the skin of another animal. That is what occurs to me as the possible object of the experiment.

5622. Surely that is a totally different experiment from artificially uniting the animals, so that they have to live together. To remove a piece of skin from one animal to another is a totally different experiment from the one which I referred to?—The first question would be, whether under the most favourable circumstances union would take place in such transplantation? A piece of skin completely removed might very probably slough away, and not continue to live.

5623. (*Mr. Huxley.*) Is it not the case that such experiments as those which Mr. Hutton has just been describing have recently been undertaken in this country for the purpose of putting that well-known doctrine of Mr. Darwin of pangenesis to the test; is that within your knowledge?—It has not come under my knowledge. As I said, I have not kept up my knowledge of experimental physiology of late years, excepting in one or two departments.

5624. (*Mr. Forster.*) Do you not think that there may be some danger that a physiologist would be inclined to try experiments, I mean painful experiments, simply with a sort of discovering idea, to find out what will happen, without having any definite notion of producing a result which would bear upon some question affecting life or pain?—I am quite sure that that has been the case, and is the case.

5625. And would you not consider that that is a thing which is open to very great objection?—Certainly.

5626. (*Mr. Huxley.*) Is that the case within your knowledge, because physiological experimentation nowa-days is so troublesome and complicated a thing that, so far as I have known physiologists, they do not generally undertake an experiment without some definite purpose. Of course if it is within your knowledge, I have nothing further to say?—My impression is that a very large number of Magendie's experiments certainly were made simply in this way, performing a certain section and then looking out for results, not with any distinct conception of what the object of that experiment was.

5627. Then it is the case that Magendie's experi-

Mr. W. B. Carpenter, C.B., M.D.

11 Dec. 1875.

ments were made 40 years ago, and that since that time experimental physiology has completely changed front, if I may so express it. Men now have far more definite objects and much clearer views in respect to living operations than they had then?—My impression is that there will always be a tendency of the kind referred to, arising, I may say, out of an imperfect scientific conception, on the part of a class of students having no particular objection to the performance of such experiments. I have myself seen in certain instances, a perfect callousness to animal suffering, before the introduction of anæsthetics. I will not mention names, but I have seen a callousness which very strongly repelled me; and this when important experiments were being performed. But that, I think, does not constitute any adequate reason against the performance of well-considered experiments with a definite object.

5628. From your acquaintance with physiological science in this country, may I ask whether it is your opinion or not that physiologists as a rule, if they had the alternative before them of performing experiments with pain, or removing it, would choose the alternative of removing it?—Most certainly, as far as I am acquainted with the present state of things, they would choose the alternative of removing it.

5629. That taking the English physiologists with whom you are acquainted, they would look upon it as a matter of duty to do so?—Certainly.

5630. You mentioned just now Dr. John Reid. I think you were perfectly acquainted with him?—Very intimately.

5631. Have you had brought under your notice statements that have been recently circulated respecting Dr. John Reid, holding up some expressions of his during his last illness, when, as I need not tell you, he was suffering from terrible agony, with the intention of showing that he considered those sufferings a judgment upon him for his experimentation upon animals?—I would not say but that he might have used some such expressions in the agony he experienced during the latter part of his life; he suffered under one of the most painful diseases which can affect a man, cancer of the tongue, and in the most severe form; but I have letters from him, written within a few weeks of his death, in which he refers to his previous work with the greatest gratitude at having been permitted so far to complete his physiological researches, and to establish by their means truths of great scientific importance.

5632. (*Mr. Hutton.*) May I ask this question? We have had experiments described to us in which dogs have been subjected for nine hours to an amount of suffering that we could not quite determine, because they were under the influence of curari, and we do not know what the influence of curari is, simply for the sake of testing the action of different drugs, rhubarb and so on, on the liver, on the secretion of bile. Now is that, do you think, a sufficient end for the infliction of severe suffering, supposing the suffering inflicted was severe, for that length of time?—I should say so certainly, because the question of the action of the liver, and the function of bile in digestion, and the influence of different remedies upon the secretion of bile, is one of the most important inquiries in its relation to the whole of practical medicine.

5633. And do you suppose that if the drug was introduced into the intestine, and did not go through the ordinary process of digestion, you could rightly infer from the effects so produced what would be the case if it were introduced into the stomach, and did go through the ordinary process of digestion?—Digestion does not take place in the stomach alone, but in the whole of the intestinal canal; and it is very important indeed to determine the place at which the different portions of that digestive process take place, and the effect of the secretion of bile upon its successive stages, in the stomach, in the small intestine, and in the large intestine, and the effect of various medicinal agents upon each of those stages. Therefore for certain purposes I should say that it was quite right that these drugs should be introduced into the intestine, and should not have gone through the stomach. I am quite aware that this is a subject upon which some very able experimenters have been engaged, one particularly with whom I have conversed many times on the subject; and I believe that these experiments, of which I think an account was given at the last meeting of the Medical Association at Edinburgh, are felt in the profession at large to be of the greatest value in leading towards (I do not say that they have yet entirely succeeded) a definite guidance in the administration of remedies affecting the secretion of bile and its operation in digestion.

5634. Are you prepared to express any opinion as to whether those experiments might not have been made, with due allowance for the effect of anæsthetics, under anæsthetics?—I think that they would probably have had to be made under both; because the state of the nervous system is one that has a most important bearing on the secretive action; and it would be impossible to say, from the result of experiments under anæsthetics, what would be the result when the nervous system was in full activity.

5635. (*Mr. Huxley.*) You mentioned just now, in terms which I was glad to hear, Dr. Brown-Séquard. You were acquainted with Dr. Brown-Séquard when he was in London I think?—I have been acquainted with him for the last 30 years.

5636. But you knew him in London, did you not?—Long before he came to London.

5637. You are aware that during his short stay in London he had a very large practice?—Yes.

5638. He acquired a great reputation among persons suffering under nervous disorders?—Yes.

5639. And his practice in your opinion, I doubt not, justified that reputation?—Yes.

5640. His special power of treating nervous disorders arose entirely from his intimate acquaintance with the physiology of the nerves, did it not?—Yes.

5641. That intimate acquaintance being derived from experiments?—Yes. I may mention that Dr. Brown-Séquard first came to me very soon after Dr. John Reid's death; he was in London at that time, certainly 30 years ago; and I then said to him, "Your "mode of experimentation seems to me more that of my "late friend Dr. John Reid than that of any other "physiologist that I am acquainted with," and he said, "You could not pay me a greater compliment."

5642. In any legislation upon this question, I presume you would think it very desirable to draw a clear distinction between experimentation upon living animals so far as they are sensitive, and experimentation upon living animals generally?—Certainly.

5643. Because suppose it were enacted that in certain cases experimentation upon living animals should not take place, a strict interpretation of that phraseology would of course prevent experimentation upon animals in which general life still remains, but without any life of the nervous system?—Certainly.

5644. And I presume you do not think it desirable to prevent experimentation of that kind?—Certainly not. It is there that the difficulty of drawing the line seems to me to become the greatest obstacle to legislation.

5645. (*Chairman.*) As Registrar of the London University, will you tell us generally what is the relation of the London University to the Brown Institute?—The Senate of the University of London are Trustees, under the Will of Mr. Brown, of the Institution for the establishment of which he left a large sum of money to be administered by the Senate.

5646. What were Mr. Brown's general objects?—The provisions of his Will were to the effect that this sum, the residue of his fortune, was left for the establishment of an Animal Sanatory Institution; the special objects of which were to be the investigation and study and, as far as may be, the cure, of the maladies and injuries to which any quadrupeds or birds useful to man may be subject.

Mr. W. B. Carpenter, C.B., M.D.

11 Dec. 1875.

5647. Have questions arisen in the Senate of the University with regard to the present administration of that Trust?—Yes.

5648. Are those questions finally disposed of?—The first question is, I believe, finally disposed of. It was this: Mr. Brown provided by his Will that animals shall be received as patients into the institution; he also made special provision for the purchase of diseased or injured animals or their carcases for pathological study, and he left the direction of that study to a Committee to be appointed by the Senate. It came to the knowledge of a member of the Senate that the artificial induction of disease was being practised,—the disease called pyæmia, for example. It was urged that this practice was inconsistent with the provision of Mr. Brown's Will, that kindness to the animals committed to the charge of the Professor-Superintendent should be a general principle of the institution. It was replied by other members of the Senate, that this principle had reference to the animals received as patients, and that the procedure objected to was one which in the present state of animal pathology it was necessary to take, for the complete investigation of disease, although not provided for specially in Mr. Brown's Will; so that these inquiries stood upon a different footing from the treatment of animals received as patients.

5649. Now upon that were legal opinions taken?—Upon that a legal opinion was taken. Two cases were drawn out, one under the direction of the member of the Senate to whom I have referred, and the other by myself chiefly as representing the Committee of the Brown Institution. These were placed before Mr. Charles Hall, who is now Vice-Chancellor. It was agreed on both sides that his opinion should be considered as decisive; and Mr. Charles Hall gave it as his opinion that the distinction was a valid one, between the animals received as patients, and the animals upon which this pathological inquiry was being prosecuted; and that the concurrent testimony of pathologists, that such artificial induction of disease has now become an essential part of the investigation and study of the diseases of animals, fully justified the carrying on of this research as a part of the proper business of the Brown Institution.

5650. And upon that opinion the Senate acted?—Upon that opinion the Senate have acted.

5651. Will you tell us the other matter that is in suspense?—A member of the Senate brought under its notice certain statements, which statements I should say had been published, in part at least, in a medical periodical.

5652. Upon that was an inquiry instituted by the University?—The Senate appointed a committee.

5653. Has the report of that committee yet been dealt with by the University?—It has been placed before the Senate, but the Senate has postponed the consideration of it.

5654. Until after the report of this Commission?—Until after the report of this Commission.

The witness withdrew.

Adjourned to Monday next at 2 o'clock.

Monday, 13th December 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. Lord WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

THOMAS LAUDER BRUNTON, M.D., D.Sc., called in and examined.

T. L. Brunton, M.D., D.Sc.

13 Dec. 1875.

5655. (*Chairman.*) You are Lecturer on Materia Medica in Saint Bartholomew's Hospital, are you not?—Yes.

5656. And you have paid particular attention to the subject which is referred to this Commission?—Yes.

5657. Generally your attention has been directed to physiology, and under the head of physiology to the department of pharmacology?—Yes, more especially.

5658. In pursuing your researches do you make any considerable use of experiments upon living animals? Yes, very considerable use.

5659. In the way of administering drugs to living animals?—Yes.

5660. I suppose, therefore, that painful operations upon living animals do not fall very much within your particular experience?—Operations do fall within my experience, because in trying to make out exactly the action of the drug, one is obliged not merely to give it to the animal and watch the general effect, but also to perform certain experiments, certain operations, in order to watch the effect of the drug before and after the performance of such operations, and thus to ascertain the action of the drug upon particular parts of the body. In this way we make out precisely where and how the drug acts.

5661. Then operations are performed by you upon living animals for the purpose of exposing to view the particular portion of the interior of the animal on which you wish to witness the effect of the drug?—Sometimes.

5662. Are those operations performed under an anæsthetic?—Yes, almost always.

5663. And if there are any exceptions is that for some special reason?—Always.

5664. Then do I rightly understand you to say that regard is had to the probable suffering of the animal, with a view to prevent it altogether or at least as much as possible?—To prevent it as much as is at all possible.

5665. Then as a matter of fact is much pain in the way of operations inflicted upon living animals in the course of your researches?—No; the chief pain is simply due to the action of the drugs themselves.

5666. The object being to test the operation of the drug upon the lower animals instead of testing it upon man?—Yes.

5667. Has that particular branch of research been very much developed of late?—I will not say precisely the number of years, but lately it has developed very rapidly and made very rapid progress.

5668. Can you give us any instances in which the making of those operations upon living animals has been very conducive to the welfare of the human race?—We have had several new remedies within the last few years which have proved very serviceable, and I think I may say have been introduced into our pharmacopæia solely on account of their action having been previously ascertained upon the lower animals.

5669. Sir James Paget told us that in consequence of some observations of yours upon nitrite of amyl that fatal and distressing malady *angina pectoris* has been reduced more within the domain of medical control than it had been previously; that is so, is it?—Yes, that is so.

5670. Can you mention any other instances?—The

T. L. Brunton, M.D., D.Sc.

13 Dec. 1875.

introduction of chloral, which has now become very useful, and is a very commonly employed hypnotic, is an instance. Then we have the introduction of atropia as a remedy for salivation. We have the introduction of apomorphia as an emetic. We have also the introduction of the Calabar bean into medicine. Those are the chief instances that occur to me at present. But there is also one other instance in which such experiments have proved very useful, namely, the discovery by Claude Bernard of the method by which carbonic oxide produces poisoning. When a charcoal brazier is lighted you get two sorts of gas produced, carbonic acid and carbonic oxide. Now if a person is suffocated with carbonic acid, as is the case if a man falls into a brewer's vat, for instance, it is quite sufficient in order to resuscitate him, simply to keep up artificial respiration for some time. With carbonic oxide, on the contrary, this is not sufficient, because Bernard discovered that carbonic oxide forms a compound with the blood which is incapable of taking up the oxygen of the air in the lungs, so that the blood is for the time rendered useless. This discovery was applied by Hüter, of Berlin, in a case of charcoal poisoning. A man was poisoned by a charcoal brazier one night; Hüter was brought in before the man was quite dead; he kept up artificial respiration, but saw that this was going to be of no service, because the blood was so saturated with this carbonic oxide that artificial respiration was doing little or no good; he, however, knew that if he withdrew some of this poisoned blood and replaced it by fresh blood then the artificial respiration would have its proper effect; he accordingly did so and saved the man's life. That man would certainly have died if Claude Bernard had not previously discovered that carbonic oxide acted in such and such a way upon the blood.

5671. (*Lord Winmarleigh.*) I presume from what you say that that discovery was made by an experiment upon some animal?—Yes.

5672. What animal?—I believe Bernard used various sorts. So far as I remember it was chiefly upon dogs that he experimented. This carbonic oxide has the same general action upon all animals, but if I remember rightly it was chiefly dogs that Bernard used in his experiments.

5673. Could you describe to the Commission what the particular experiments were by which that result was brought out?—The way in which it was discovered was this. Bernard found that when animals are poisoned by carbonic acid the blood is of a dark colour, and that when they are poisoned by carbonic oxide the blood is of a cherry-red colour, and remains of a cherry-red colour. Being struck by this curious appearance of the blood, he set to work to investigate the amount of gases contained in the blood, and in this way he discovered that carbonic oxide formed a compound with the blood and prevented the blood from taking up oxygen as it usually does.

5674. That could not have been discovered without great danger by an experiment on the human being, I presume?—I should say it was quite impossible.

5675. You stated just now that the chief pain inflicted upon animals in your department is by the operation of the drug itself upon the animal, not by the incision or anything else that is done to expose the experiment?—No; because the way in which I perform my experiments is this: I give the animal chloroform, and I do my operations whilst it is under its influence; but then I am obliged to allow the animal to come out of the chloroform in many instances, because otherwise the action of the chloroform would so interfere with the action of the drug that I should not be able to separate them. In some cases I am able to keep the animal thoroughly under the influence of the anæsthetic the whole time, by giving it a large dose of chloral and giving it the drug afterwards. Then I get the two actions combined, that of the chloral and that of the drug; but in those cases I am able to separate the two. I know what the chloral alone would do, or rather I do not know precisely, but I have a pretty fair idea, and then I know what the two together do, and in this way I ascertain the action of the drug; but it is sometimes impossible to do so. One must sometimes give the drug after the animal has come out of the chloroform.

5676. But for the purpose of that particular experiment you have to perform an operation which would be of a painful nature but for the chloroform which you give?—Yes.

5677. You say that you are obliged to keep the animal alive after it comes out of the anæsthesia for the sake of seeing the operation of the drug?—Yes.

5678. Is the incision that you have made for that purpose allowed to remain open?—Sometimes.

5679. And does that cause no pain?—It certainly will cause a certain amount of pain, but, as we all know, if we get a cut on the finger it is the cut itself that a person objects to. For example, in taking off a finger a person would say, "Well, I must have chloroform; I cannot stand having my finger cut off without chloroform." He does not mind the pain afterwards; it is the cutting that he dislikes.

5680. You think then that the animal does not suffer any excruciating pain, at any rate, when recovered from the anæsthesia while you are examining the operation of the drug?—No. I simply judge from myself, or from men who have had operations done. It is the performance of the operation that is the exceedingly painful part, and after the operation is over they do suffer a certain amount of pain, but still it is quite bearable; and I judge that in animals it is the same.

5681. What drug is it in your opinion that creates the greatest amount of pain by its operation upon the particular part on which you wish to make the experiment?—I should think that probably the most powerful thing with which I have experimented is the poison of snakes.

5682. Would you describe to the Commission what is the usual result of your experiment?—The animal first seems to get heavy and depressed, and then vomits; sometimes the vomiting is very violent, and then by-and-bye after a little while you get twitchings in some animals.

5683. Then do you use anæsthetics in that case?—No. I should use an anæsthetic if I were obliged to do any painful operation, any cutting operation, but then I could not use an anæsthetic when experimenting on snake poison, because the anæsthetic would completely mask the operation of the poison itself.

5684. Is that an experiment of very long duration?—Well, the animals generally die in about half an hour.

5685. It does not exceed half an hour altogether?—I think not. I am not quite certain that that is quite as painful as poisoning by strychnia.

5686. What kind of pain is it in that case; is it from convulsions?—In strychnia there are convulsions. It is somewhat difficult to say which will cause the most pain. It is possible that although in cases of poisoning by strychnia during the operation of the strychnia there may be pain, the convulsions on the other hand may not be painful, because it is difficult to separate the appearances due simply to the action of the drug and the appearances which might be produced in consequence of an indirect effect, that is to say, in consequence of pain occasioned by the convulsions.

5687. But you undertake to say that as regards the general run of your experiments they are quite the exceptions where there is any pain necessarily attached to them from the operation?—Yes; quite exceptional.

5688. Do you think that you have given us the principal instances, or are there any others?—I think I have given you the principal ones.

5689. Have you any experiments on hand now with any special object of more than common importance?—Not at present. Some time ago Dr. Fayrer and I were engaged in a research on the action of snake

T. L. Brunton, M.D., D.Sc.

13 Dec. 1875.

poison, with the object of ascertaining whether we could get an antidote to that or not.

5690. Have you ever made any experiments with regard to hydrophobia?—No.

5691. Do you know whether any experiments have been made with a view to the prevention or to the cure of hydrophobia?—There may have been but I am not aware of any. It would be exceedingly difficult to experiment upon that.

5692. (*Mr. Forster.*) Are you a lecturer, may I ask, at St. Bartholomew's Hospital?—I am a lecturer at St. Bartholomew's Hospital.

5693. I have got before me the return that was sent from that hospital to the questions which have been asked by the Commission, and to this question, "State whether, and in what proportion, the animals "are in the state of anæsthesia; distinguish the "case of frogs; and also what anæsthetics are em"ployed?" the answer sent in is, "In all cases of "class demonstration the animals are in a state of "anæsthesia. The animals are killed at the end of "the demonstrations. The anæsthetics employed are "wourali, chloral, chloroform, and ether." Are you in the habit of employing wourali in those cases?—Sometimes.

5694. Do you think it is an anæsthetic?—To a certain extent I think it is. I do not think it is an anæsthetic in the same degree as chloral, opium, or chloroform.

5695. We have had a great deal of evidence before us showing difference of scientific opinion as to whether it is an anæsthetic, but on the whole the balance of evidence in the view of Claude Bernard seems to show that while it stops muscular motion it does not banish pain?—I think Claude Bernard is mistaken.

5696. You observe that the answer which I have just read to you, as it stands, seems to show that for the purpose of preventing pain a drug is given which may not prevent pain at all?—The reasons for believing that Bernard has been mistaken are that if you give a frog wourali and stop the circulation in one part of the body so that the wourali only gets to one part and leaves the other part unpoisoned, pinching the skin of the poisoned part does not cause the animal to kick as pinching it on the unpoisoned part would do. Or if you take two frogs and treat them in the same way, but poison the upper part of one frog and not of the other, you will find that the nerve-centres seem to be to a certain extent paralysed; the wouralised frog does not kick on the application of a painful irritant, although it might perfectly well do so. These facts were discovered by Von Bezold so long ago as 1860, and by Schiff and Lange in 1870.

5697. Without entering into the scientific evidence on one side or the other, I will ask you this question; do you think it is a matter of certainty that wourali is an anæsthetic?—No, it is not a matter of certainty.

5698. In what cases do you employ it in demonstrations?—I very rarely employ wourali in demonstrations.

5699. Will you be kind enough just to look at that answer (*handing the return to the witness*) and tell me to what cases that answer would seem to refer?—To frogs. I do not think that I ever employed any wourali in class demonstrations except in the case of frogs; and in the case of frogs I can demonstrate, and did demonstrate this last spring to my class, that wourali certainly paralyses the sensory nerves as well as the motor.

5700. The answers that are given to the inquiries in that return would seem to give the impression that anæsthetics are not employed at St. Bartholomew's Hospital for the purposes of investigation; because to the question "When not in that state, the reason why not?" the answer is "See above." Do you imagine that ought to be the impression given?—The reason of that is simply this, that I have been absent on the continent, and Dr. Moore I should say probably did not know what to say; I and Dr. Legg are the only persons, I believe, at St. Bartholomew's who do any experimental work for original investigation, and Dr. Moore did not know exactly to what extent I used anæsthetics in my laboratory in original investigation, so that he was not able to give a satisfactory answer to that question.

5701. Then the correct answer would have been that anæsthetics are used whenever they can be used with safety to the experiment?—That would have been the correct answer. I got a notice to be present at a meeting at St. Bartholomew's, but unluckily I did not get the notice until after I came back on Saturday, and the meeting was held a week or two ago.

5702. How often do you have these class demonstrations with living animals, do you think?—I give about eight lectures in the course of the year. I lecture once a week after Christmas; and I give from 8 to 10 lectures.

5703. And have you lectured upon your particular branch, the pharmacological branch, of physiology?—Yes.

5704. I suppose you give drugs in the presence of the students sometimes?—Yes.

5705. In those cases I suppose you are unable to give anæsthetics?—The same rule applies to that as to what I said before. If there is any operation to be done I use the anæsthetic. If there is no operation to be done and I have simply to show the action of the drug, I do not give the anæsthetic.

5706. Do you wish to give any explanation of this answer, made in the return sent from your hospital, that "in all cases of class demonstration the animals are in a state of anæsthesia"?—It is so very nearly true that it hardly needs correction; and the reason of it is this, that in the demonstrations that I give in winter I use anæsthetics in all cases. In my summer lectures, when I am giving a general course and when I show the action of drugs or would show it, the only one that I really do show without an anæsthetic is the action of prussic acid; because I lecture only on the inorganic materia medica, and so I am precluded from showing the action of strychnine and picrotoxine and other poisons which I should show to the class if I lectured on organic materia medica as well; therefore as the case at present stands, the only instance in which I exhibit the general action of a drug to the class without the use of an anæsthetic is in the case of prussic acid.

5707. I suppose you mean that there is immediate death in that case?—It is immediate death.

5708. (*Mr. Hutton.*) With regard to the lecturer who does show the action of strychnia and picrotoxine would he exhibit the action of those drugs without anæsthetics or not?—He does not show the action.

5709. (*Mr. Forster.*) Then in fact there is not before the students of St. Bartholomew's Hospital any demonstration of the effects of strychnine on living animals?—So far as I know there is not. On second thoughts, I believe that they are shown by the Lecturer on Forensic Medicine.

5710. (*Sir J. B. Karslake.*) You referred to some cases in which animals have been subjected to the gases from a brazier of charcoal; that I presume could not be done when they were under anæsthetics?—Yes it might have been done, but there is this difficulty about it, that chloroform itself has been discovered to have an action upon the blood; and then there is this further reason against doing it so, that it is well known that death by charcoal poisoning is almost painless.

5711. I was just going to ask you the question what the amount of suffering of the animal was when he was subject to poisoning by charcoal?—I believe there is no suffering. The notion that there is no suffering prevails so widely that that is a very common method of suicide in France.

5712. It is always supposed in those cases, is it not, that there is no pain?—It is supposed that there is no pain.

5713. (*Lord Winmarleigh.*) The pain is in the recovery, I suppose?—Yes; so far as I remember, in that case in which Dr. Hüter saved a man's life he

T. L. Brunton, M.D., D.Sc.

13 Dec. 1875.

did suffer some pain, but I will not be positive as to that.

5714. (*Sir J. B. Karslake.*) In the case of those animals operated upon by Claude Bernard the only pain they suffered, I suppose, was the pain involved in drawing a certain amount of blood from the animal and transfusing healthy blood?—Bernard did not transfuse healthy blood; that was the application of Bernard's discovery which was made by Hüter.

5715. No great pain was involved, I suppose?—No.

5716. In the cases in which you do demonstrate to your class, do you think it is essential that they should see the operation and not only obtain a knowledge of it by reading?—I think it is. It makes a very great difference to the student whether he sees it or simply hears it. If he simply hears it he will pick it up for the time being, and will be able to pass a very good examination; but what we want is that he shall learn it so as to remember it for his whole life.

5717. In the cases to which you confine your demonstration then, you think it is essential that you should make the experiment before the class?—Yes. If I may give the example of prussic acid which I do show, the only one in which I do not use an anæsthetic, it is very well to tell the student "If you get a case "of prussic acid you have to do this, that, and the "other;" but what I do is this: I take the animal, give it the prussic acid, and go through the whole process of trying to recover it. I proceed with the animal, in fact, exactly as I should do with a human being, so that I think the students in that case will remember that if they are called in to a case of poisoning by prussic acid, they have to do this, that, and the other, and they will remember it much more vividly than if I simply told them.

5718. What are the animals which you chiefly use for the purpose of these experiments?—Rabbits and cats.

5719. (*Mr. Hutton.*) Your experiments for original research are almost entirely private experiments, are they not?—Almost entirely.

5720. Can you give us the least idea on what scale they have been conducted?—The number of animals employed varies enormously according to the research. In some researches one will use only a few animals, but in others you will use a great quantity.

5721. What is the largest number used by you in scientific research for a single experiment?—I think the largest number is 90; that was one series of experiments. I was trying to discover the pathology of cholera.

5722. (*Mr. Forster.*) What sort of animals did you use for that purpose?—Cats.

5723. (*Mr. Hutton.*) Do you mean that you poisoned 90 cats with cholera fluid?—No, I set about the investigation in a different way. It was discovered by Moreau that by performing a certain operation upon the intestine you could get a discharge into the intestine. This discharge was discovered by Kühne to be exactly the same as was found in the intestine after cholera; so I thought, if we can find out the exact part of the nervous system that is concerned in causing this discharge, we shall probably be able to find out the part of the nervous system concerned in cholera, and having once found that out we may be able to get a drug that will act upon it and thus cure cholera.

5724. You performed this operation on the 90 cats under chloroform, I suppose?—Yes, under chloroform. I must say, however, that the animals were allowed to live for four or five hours after they recovered from the operation.

7525. And to live, I suppose, in a certain amount of pain and discomfort?—They suffered a certain amount of discomfort and possibly pain, indeed, probably pain, though I do not think very great pain; I think probably not much more pain than a man would suffer who had perhaps a bad attack of diarrhœa.

5726. They did not die then in the same sort of agony that a cholera patient dies in?—No, because only a certain portion of the intestine was operated upon.

5727. Did they die as the result of the experiment?—They were killed at the end of the four or five hours.

5728. Now have those operations resulted in any beneficial discovery?—Not yet; they are not finished.

5729. They are still going on, are they?—They are still going on; and it is, perhaps, not to be very much wondered at, because the subject is an exceedingly difficult one, and it would take a number of experiments to make it out.

5730. And those experiments are performed in your own laboratory at St. Bartholomew's?—Yes.

5731. (*Mr. Forster.*) What makes you choose cats for those experiments?—They are very good animals to experiment upon, and they are cheaper than rabbits.

5732. Why are they good animals?—They are a convenient size, and you get the results very definitely. If you do your operations rightly you are sure of getting the results.

5733. Do you think that the cat is on the whole better for it than the dog?—You cannot get dogs.

5734. (*Mr. Hutton.*) How do you procure your cats?—They are supplied to me by a man.

5735. Who steals them for the purpose, I suppose?—I make no inquiries.

5736. And have you occasion ever to sew up the lips of cats, or anything of that kind?—No.

5737. How do you put them under chloroform?—It is as easy as possible; cats are the easiest animals in the world to manage. All you have to do is to put the animal quietly into a milk pan, stroke it, put a towel over it, and sprinkle the chloroform quickly over the towel, and the vapour of the chloroform being heavier than air descends, and the animal goes quietly under the chloroform. The only care one has to take is that one does not keep it under it too long.

5738. How do you apply it to a dog?—If it is a small dog I generally put it under a bell jar with a sponge or a large piece of blotting paper dipped in chloroform. If it is a large dog I use a packing case with cracks in the bottom, which are stopped with blotting paper which is saturated with chloroform.

5739. (*Mr. Huxley.*) Have you ever found any difficulty in applying chloroform to frogs, because we have been told that there is a difficulty in it?—No; with a bell jar you can do it without difficulty.

5740. (*Mr. Forster.*) Why do you use wourali then in their case and not chloroform?—If I use chloroform I do not use wourali; I use one but not both.

5741. As far as regards the success of the experiment, you might just as well use chloroform for a frog as wourali, I suppose?—No, not always; it depends on what you are going to do. For some experiments you must use wourali when you want to get the nerves paralysed. You do not get that with chloroform. The action of the chloroform is upon the brain; the action of the wourali is upon the nerves. If you simply want to do an experiment which in another animal might cause pain, and which you are afraid might cause the frog pain, you may use chloroform.

5742. Then the purpose for which wourali is used is in order to keep the animal quiet, to make the experiment an easier one to conduct?—Yes, in frogs and in the higher animals it is to get rid of some of the effects which might be due to irritation of the nerve centres. For example, this is the case in some physiological experiments that have been made in Germany, by irritation of various parts of the nervous system, of the upper part of the spinal cord. You want to ascertain the influence of that part upon the vascular system generally, the system of blood vessels, and you want to ascertain that alone. If you irritate this upper part of the cord after you have given wourali you only get the action upon the blood vessels, but if you were to irritate this part without giving wourali previously, you would get the irritation conducted all down the ordinary motor nerves, and get all the muscles set into violent action; the action of the muscles would react upon the vessels, and you would get the whole experiment disturbed.

5743. Is there anything to prevent your giving both drugs, or giving them mixed together, so as to stop the pain by the chloroform and the nervous movement by wourali?—Yes, there is, and it is this:—in very many of those experiments you want to ascertain what is termed the reflex action; that is to say, that an impression is made upon a nerve and goes up to the cord and is transmitted down. Now chloroform acts upon the reflex centres and abolishes their influence completely; so that if you give the wourali which paralyses the ends of the motor nerves, and give the chloroform which paralyses the reflex centres, you deprive yourself of the possibility in many instances of making satisfactory experiments.

5744. But are there not many instances in which you give wourali simply for the purpose of getting the animal perfectly quiet?—Yes, those instances which I gave.

5745. But if it is done for the purpose of getting the animal perfectly quiet, could not chloroform be given also?—No, for that very reason; if you were to give chloroform the experiment would be at an end, you would have abolished the action of the reflex centres, and thus you might as well not do the experiment at all.

5746. (*Mr. Hutton.*) What would you say was the next largest series of experiments that you made after that on cats with reference to cholera, which you say is still going on?—The next is on the action of the snake poison.

5747. And how many and what kind of creatures have you used for that purpose?—All sorts,—rabbits, guinea-pigs, frogs, dogs, pigeons, fowls. The number I do not exactly remember. When I said just now that I used 90 cats, I should have said that was in one series, but I am now at the third series. The number 90 is not the whole that is included in the investigation; I have used a much larger number for investigating the subject of cholera than 90.

5748. What would be the total number of animals then used for these cholera experiments, and have they been all cats in all the series?—Nearly all. I could not exactly say the total number without looking up the reports of the British Association. I think I can fill in that afterwards. For the snake poison experiments I should think I have used about 150.

5749. Of different kinds of creatures?—Of different kinds of creatures.

5750. (*Mr. Huxley.*) In experimenting on snake poison you do not require that the animal should be bitten by the snake; you simply inoculate the poison?—Inoculate the poison simply.

5751. (*Mr. Hutton.*) After the snake poison what would be the next most important series of your experiments?—I think possibly those on nitrite of amyl and nitrites generally.

5752. Had you to use a great many animals for those investigations?—No, not so many, a very much smaller number; because you get very decided results. It is when you get slight differences between your different experiments that you have to use such a large number.

5753. Were you able to use anæsthetics with the nitrite of amyl experiments?—Sometimes, but generally I think I did not, because a number of these experiments were made in a laboratory in Germany, and the professor considered that it would not be at all advisable, as one would get the result complicated. By using chloroform along with nitrite of amyl one would have got the result very much complicated.

5754. For the purposes of the nitrite of amyl experiments you have to expose the arteries, have you not?—Yes.

5755. And is not that a very painful process?—I think it is somewhat painful.

5756. And the effect of the nitrite of amyl was in dilating the smaller arteries?—Yes.

T. L. Brunton, M.D., D.Sc.

13 Dec. 1875.

5757. (*Chairman.*) Could you not have performed the operation of exposing the arteries under an anæsthetic?—Yes, and the only objection to that is this: that after you have given the animal chloroform it does not come quite out of it for a very long time, there is always a residual action, and where you are experimenting with such a substance as nitrite of amyl, which belongs to a series of bodies nearly allied to chloroform, you would be very apt in such a case to get the residual action of the chloroform interfering with that of the amyl.

5758. Supposing you had used ether?—There again you get the same difficulty, indeed rather worse.

5759. Do I rightly understand you to say that if you were to do it over again you would not use an anæsthetic?—I should certainly feel myself obliged to do several experiments without any anæsthetic, on account of the residual action of chloroform.

5760. (*Mr. Hutton.*) Do you consider that residual action to be so considerable that the use of chloroform would have vitiated Dr. Rutherford's experiments on drugs now going on, or recently going on in Edinburgh, on the action of drugs on the liver?—No.

5761. They were all under wourali, and not under chloroform?—I do not think that chloroform would interfere much with those experiments.

5762. Do you think that, allowing for the action of chloroform, those same experiments might have been made under chloroform instead of under wourali?—I should be chary of giving an answer to that question for this reason, that I have not given sufficient attention to it to be quite certain; just thinking over it I would say possibly they might.

5763. I understood that all your experiments on the action of drugs, even those on the action of drugs on the liver, have been made under chloroform?—Yes, but I have made very few on the liver. As to the experiments that I have done, I have only made I think about five or six original experiments on the liver, and those were done under the use of chloroform.

5764. And in those cases you did not think the action of chloroform injurious?—I thought that it might interfere a little with it, but then it was a different sort of research from that of Dr. Rutherford. It could not interfere so much with mine as it might have done with his.

5765. Is it not true that wourali itself excites the secretions?—Somewhat.

5766. So that there would be a residual action to allow for in its use?—Yes.

5767. (*Mr. Huxley.*) Would there not be some danger of disturbing the condition of the circulation in the liver if you kept the animal under chloroform for the number of hours which would be necessary in Dr. Rutherford's experiments?—Yes, I was forgetting that; there would be the difficulty that you would very probably get more or less an amount of venous congestion; my experiments did not last so long.

5768. (*Mr. Hutton.*) Still you would not think that the first operation might not have been performed under chloroform; I mean the exposure of the biliary duct, even in the case of Dr. Rutherford's experiments?—To answer that question I should have to run over the whole literature on the subject to know exactly what had been made out about the action of chloroform. I do not think I would give a definite answer to that.

5769. I observed that you distinguished chloral as a hypnotic from an anæsthetic; would you tell me precisely what you meant?—Chloral in small doses produces sleep, apparently a natural sleep, and in such doses it is a hypnotic; you can wake a person readily from such a sleep. If you give an animal a large dose you produce a greater effect; the sleep is then so profound that the animal will not awake. You may cut it into pieces, or do what you please with it, it will lie as if dead. It is an anæsthetic for animals, but you cannot use it safely as an anæsthetic for human beings, because these animals that have got so large a dose of it do not recover.

5770. But you give it in doses sufficient to make

T. L. Brunton, M.D., D.Sc.

13 Dec. 1875.

it an anæsthetic?—I give it to animals as an anæsthetic; but the doses I give to animals are such as I would not dare to give to human beings.

5771. Do you regard opium as an anæsthetic or only as a hypnotic?—As an anæsthetic assuredly.

5772. Is it in moderate doses an anæsthetic?—Yes, I should say decidedly.

5773. Why is it then that chloroform is so very much more used than opium for the purposes of operations?—Because, to begin with, if you give a dose of opium sufficient to render a person anæsthetic you keep him soundly asleep for many hours, and then he will awake with a deranged digestion and a bad headache, and those are not the conditions in which you want to have any patient whom you wish to recover from the effects of an operation.

5774. But chloroform disorders the stomach, does it not?—But its effects are much more transient than those of opium.

5775. And it is much less dangerous, I gather from you?—Much less dangerous.

5776. I notice in this Handbook of Physiology, of which you are part editor, that you put two asterisks to a great many of your experiments which you describe as "best suited for demonstration"?—Yes.

5777. I want to ask you a question or two about some of those; for instance, the experiment on page 470, "demonstration of the functions of the "*chorda tympani* and sympathetic fibres of the "submaxillary gland of the dog", where you first subject the dog to chloroform; is not that a very long experiment?—A very long experiment.

5778. Can you keep the dog under chloroform during the whole of that experiment?—Perfectly well.

5779. Have you to have a special assistant for that purpose?—Yes; you do not want a trained assistant, but just the ordinary laboratory servant.

5780. And in the other experiments of that kind, some of them I think very long, that are also marked as demonstrative experiments, the same is true, is it, that you employ an assistant to keep the animal under chloroform for the whole period?—Yes.

5781. Now when you speak of them as demonstrative experiments, are those experiments which you would show to an ordinary class?—Yes; all those marked with a double asterisk are such as I would show.

5782. And you would think it so easy to keep the animal under chloroform the whole time, that you would have no fear of its suffering during those experiments?—None whatever.

5783. Now I see one of your experiments on page 505, I think of the same kind, in which the animal is to recover from the chloroform; it is marked with a double asterisk, and is headed "Mode of producing "biliary fistula in guinea-pigs;" there the animal is to recover, and you say that the animals would sometimes live for a week?—In that experiment you keep them under chloroform the whole time. The sentence, "when the bile duct is tied the guinea-pigs die "in less than 24 hours, but when it is not tied they "will live for a week," is simply a statement of the results obtained by Dr. Heidenhain.

5784. You mean that it is not one which you would have repeated?—That sentence is merely an interpolation, the same as this one,—"The bile in guinea-pigs "is secreted in very large quantities, being as much "as 7·3 grammes in an hour per kilogramme of body "weight." Both are merely statements of the results obtained, and not the experiment.

5785. You meant the animals to be destroyed before, did you?—Yes, this is shown at page 507, where you come to the end of the directions for performing the experiment. What you do is this, "sew up the "wound, leaving the free end of the canula outside." That is the end of the operation, and next comes what you have to demonstrate. I should have put the two former sentences as a footnote really. "The bile is "secreted under a very low pressure." You have now got to proceed to demonstrate this.

5786. The result is that the animal lives a long time, is it not?—No, you find at the end of the page, "if you carry the experiment far enough the animal dies."

5787. And is it the intention of the experiment that you should carry the experiment far enough for that?—Yes, if you do not pour sufficient water into the tube you can kill it.

5788. Then there are none of these experiments merely for demonstration that you take to involve suffering?—I think hardly any. There are two that do involve slight suffering. The first of those is at page 515, "Production of glycosuria by puncture of "the floor of the fourth venticle," and the other is "Moreau's experiment" at page 525; I think those are the only two.

5789. There is one in which you allow the effect of the anæsthetic to pass off, and then draw down the animal's intestines?—But if you look at that you will see that you only allow the effect of the anæsthetic to pass off so far that you get only a slight movement; that is all you want, you do not allow it to pass off so far as to cause the animal pain. All you want is to allow it to pass off so as to get a slight indication.

5790. To cause it uneasiness?—Yes, but I am not sure that it feels it; I am not sure that it is not reflex action.

5791. I think you said that the supposed anæsthetic effect of wourali was discovered as early as 1860?—It was discovered by Von Bezold, that when you gave wourali the animals did not react as they would under the ordinary supposition, under Bernard's supposition, that the motor nerves only were paralysed. He attributed this effect to the action of wourali on the spinal cord. But in 1870 Schiff and Lange made some experiments in which they showed that in frogs, at least under certain conditions, that is to say in spring frogs (we do not know why, but the effects of wourali seem more marked on the sensory nerves of frogs in spring,) you got from wourali very distinctly a paralysis of the sensory nerves as well as the motor nerves.

5792. And that is not equally clear in autumn or at other periods of the year?—Not so obvious.

5793. How long has it been your opinion that wourali is to a certain extent an anæsthetic?—Since I first became acquainted with Schiff's experiments.

5794. That was about a year and a half ago?—It is two years and a half ago.

5795. And since that time you have been in the habit of using it partially as an anæsthetic?—No; because I have had no occasion to use it. My experiments have not required it. I have used in preference the other anæsthetics, because I know that they were more thorough anæsthetics than wourali. I do not mean to say at all that wourali is such a thorough anæsthetic as the others. All I can say is that I believe it is a partial anæsthetic.

5796. And that you limit to the case of frogs, and frogs in spring, I understand?—I would limit it to the case of frogs. I do not know; I think it is probable that it also acts so in the higher animals, but we cannot tell. There is just this fact, that when animals have been operated upon under the influence of wourali they do not show so much pain after they come out as you would imagine they would do if they had been suffering all the time.

5797. (*Lord Winmarleigh.*) You are acquainted, I suppose, with a great number of gentlemen who are pursuing the same investigations as yourself?—Yes.

5798. Have you any means of knowing whether any of them agree with you in what you have just stated with regard to wourali?—I do not know. I could not state positively.

5799. May I ask whom do you allow to be present with you when you are making your experiments for investigation?—The room is so small that I have no one present excepting just the man who is helping me.

5800. You do not allow students or other persons to be present?—There is no room for them, my laboratory is about half the size of this table.

T. L. Brunton, M.D., D.Sc.

13 Dec. 1875.

5801. What is your rule with regard to destroying the animal after the experiments ?—I always do it.

5802. Invariably; you never allow an animal to recover itself for the purpose of another experiment ?—Never.

5803. (*Mr. Hutton.*) Dr. Pavy told us, I think, that the effects of poison by strychnia could be shown under chloroform, and that he did show them in his class under chloroform. Would that in your opinion show it efficiently ?—I do not think it would, because chloroform has been used as an antidote to strychnia.

5804. (*Mr. Huxley.*) Having experimented so much on poisons, I presume you have paid particular attention to the effects of opium ?—Yes.

5805. I think I am right in saying that that experiment upon the chorda tympani is occasionally performed under the influence of opium, is it not ?—Yes.

5806. Would you, having paid this attention to the influence of opium, and having been familiar with what is the opinion of those who have inquired most carefully into its effect, be of opinion that "in the "deepest narcotism produced by morphia or opium "there is no real insensibility to pain ?"—No ; I believe there is thorough insensibility to pain.

5807. If anyone stated, physiologically speaking, that as his opinion, I presume you would have no hesitation in contradicting that statement ?—No.

5808. Emphatically ?—Emphatically, however high an authority it might be.

5809. If anyone stated that persons under morphia or opium feel the pain, but they soon forget it, what would you say to that statement ?—I should ask him for the proof.

5810. If a person should say that when an animal in a physiological experiment is narcotised it is still sensible to pain, would you say that that is an accurate statement or the contrary ?—The contrary.

5811. It is a point upon which you would have no hesitation whatever ?—None whatever. With regard to that experiment on the chorda tympani, I must say that you cannot do the whole experiment under opium, you cannot show it as you could under wourali. In the description that I have given of the experiment in the handbook, I have given instructions to do it under chloroform ; but by doing it under chloroform there are several points that you cannot show. The first time that I tried to demonstrate the action of the chorda tympani under opium I failed completely in the first part. I wished to show that the irritation of the lingual nerve caused reflexly a secretion of saliva ; I utterly failed, it did not occur to me that by giving the opium I paralysed the reflex.

5812. But the second part of it, the irritation of the chorda tympani, succeeds perfectly ?—Yes.

5813. (*Mr. Hutton.*) I find that the passage in Dr. Pavy's evidence to which I was referring just now is this; he was asked at question 2143 "Have "you ever made experiments on the effect of strychnine on animals ? And he says "Yes." (Q.) And "you have proved, have you not, that death under "strychnine generally takes place from the ceasing of "respiration ?—It does. (Q.) In that case were you "able to use chloroform ?—Yes. (Q.) The chloroform did not in that case interfere with the success "of the experiment ?—No. There is an experiment "which I perform at lecture in which the animal is "placed under the influence of chloroform, and some "strychnine is introduced into the circulation whilst "the animal is under the influence of the chloroform ; "and whilst the animal is still under the influence of "the chloroform it dies immediately." What I wanted to ask you was whether you thought that that demonstration could be efficiently performed under the influence of chloroform ?—It may be so performed, but I should not think it so efficient or advisable for a class as the other course ; because in showing these actions to a class my object is, first, to impress upon the student the mode in which the poisons act, and secondly, to impress upon him what he is to do in case he gets a case of poisoning brought to him. If I were showing that to a class, I should first give the animal the strychnia, and then give it the chloroform, and show how the action of the strychnia was modified by it, instead of giving the chloroform first.

5814. But I suppose in the case of some poisons the experiment is an extremely painful one, in the case of picrotoxine, for instance ?—It is just the same as in strychnine.

5815. (*Chairman.*) You have told us that you have tried a great many experiments in the hope of discovering some antidote for snake bite ?—Yes.

5816. May I take it then as your deliberate opinion that it is by the way of experiment that we are to find an antidote, if we do find one ?—Assuredly.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock.

Tuesday, 14th December 1875.

PRESENT :

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. Lord WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

ALEXANDER JAMES SINCLAIR, M.D., called in and examined.

A. J. Sinclair, M.D.

14 Dec. 1875.

5817. (*Chairman.*) You are a physician in Edinburgh ?—I am a physician, and a Fellow and Examiner at the College of Physicians in Edinburgh.

5818. And you were a demonstrator of anatomy at the School of Medicine in Edinburgh ?—Yes, during the years 1868, 1869, and 1870.

5819. Your name has been mentioned in the course of our inquiry by Doctor Hoggan, who says that you gave him some advice on the subject of operating upon animals. I think you have had an opportunity of seeing the passage in which your name is mentioned ?—I have.

5820. Have you any observation to offer to us upon it ?—Simply this, that he made a statement which was inaccurate as to the fact.

5821. Will you be so good as to give us anything which you wish to give in the way of correction ?—He implied that I was in the habit of advising him to operate, and also of operating myself without the use of anæsthetics. Now such was not the case ; he must have mistaken my meaning when I gave him the advice that he mentions in the report that was sent to me.

5822. You altogether negative the statement that you advised him "not to have cats, because they "made such a squalling and scratching when you "began to cut them" ?—I negative the statement as far as the latter observation is concerned, I advised him not to use cats for vivisection, because I thought that the handling of them would be troublesome ;

A. J. Sinclair, M.D.

14 Dec. 1875.

that they would be troublesome animals to use for the purpose.

5823. Have you anything to say about any advice given to him respecting anæsthetics ?—I gave him no advice respecting anæsthetics.

5824. Either one way or the other ?—Neither one way nor the other, the subject was not mentioned.

5825. Then will you state what your own practice is with regard to anæsthetics ?—I have performed vivisection with and without anæsthetics; but more frequently with anæsthetics, as finding it more convenient.

5826. But is it the practice, so far as you are acquainted with it, to regard the sufferings of the animal as of importance, and to get rid of those sufferings by the use of anæsthetics wherever it is possible to do ?—I think that the use of anæsthetics offers a double advantage, which is not solely to the operator; it offers an advantage to the operator as keeping the animal much quieter, and also saves suffering to the animal.

5827. But I wished rather to limit you to this point, whether anæsthetics are, as far as your knowledge goes, used for the purpose of taking away pain as far as they can be ?—I believe they are.

5828. You know nothing to the contrary ?—I know nothing to the contrary.

5829. (*Lord Winmarleigh.*) Would you state to the Commission what are the experiments that you have chiefly been connected with which you perform without anæsthetics ?—I have performed experiments for two purposes. The first purpose was for a paper I was writing on the inhibitory action of the nerves on the secretions.

5830. Were those experiments in which anæsthetics could not have been used ?—The experiments I made for the elucidation of that subject were done both with anæsthetics and without anæsthetics. I found afterwards that it made no difference if I used anæsthetics, and I continued the experiments with anæsthetics.

5831. But when you first made the experiments you believed that they could not be made under anæsthetics ?—I used both means to ascertain first whether there was any difference.

5832. But you did that with the object of relieving pain to the animal ?—I did.

5833. Do you believe that in Edinburgh in the experiments with which you are acquainted the same feeling pervades the heads of departments there; that is to say, the persons who are most experienced in these matters ?—I think so.

5834. Do you know anything of the Veterinary College at Edinburgh ?—I do not.

5835. You do not know anything of the experiments made by the head of the veterinary department ?—I do not.

5836. Do you believe that there would be any objection on the part of the professors of physiology or medicine in Edinburgh to control being given by legislation over them ?—I am not aware.

5837. Would you yourself object ? Would you, for instance, object to an inspector ?—Yes, I would.

5838. On what ground ?—That the inspection is needless, unnecessary.

5839. You do not believe that there are any experiments made without anæsthetics except under absolute necessity ?—I do not.

5840. You speak with considerable experience on that point, do you ?—I do not speak with considerable experience, but as far as my knowledge goes of the practice of vivisection in Edinburgh that is the case.

5841. Could you state to the Commission about what number of animals you have operated upon yourself ?—Somewhere about twelve.

5842. Twelve in all ?—Twelve in all, not more.

5843. In the course of your practice ?—In the course of my practice.

5844. What have they been ?—Dogs, rabbits, and guinea pigs. I have only vivisected two dogs, and they were done for two purposes; one purpose I have already mentioned, and there was another object also.

5845. Not frogs ?—I have vivisected frogs. I beg your pardon for forgetting to mention them. I cannot tell the number of frogs which I have vivisected.

5846. Is it a great number ?—I cannot say.

5847. (*Sir J. B. Karslake.*) In the case of frogs were any means taken to prevent pain by pithing or removing the brain or using chloroform ?—In such cases where the experiments could be so done, I pithed the animal; but that is not vivisection.

5848. However, in the case of frogs, you have pithed the animal where it was possible to do so consistently with the experiment ?—Where it was possible to do so consistently with the experiment I have.

5849. Did you use experiments on living animals for the purpose of demonstration to your classes ?—No, I never had occasion to do so.

5850. Then your experiments have all been for private purposes ?—For private purposes, my own experiments.

5851. (*Lord Winmarleigh.*) Were any other parties present ?—Yes.

5852. What class of persons were present ?—Some of my pupils.

5853. In your investigations ?—In my investigations.

5854. (*Sir J. B. Karslake.*) Do you remember the fact of a conversation with Dr. Hoggan upon the subject of vivisection ?—I do.

5855. About how many years ago was that ?—In 1869.

5856. Had you had much practice in experiments on living animals yourself at that time ?—I had not.

5857. Had you made any experiments on living animals ?—I had.

5858. On dogs ?—On dogs.

5859. And had you made these series of experiments on twelve animals which you have spoken of at that time ?—I had not at that time.

5860. How many experiments had you made on living animals at that time ?—I cannot remember.

5861. At all events not so many as twelve ?—Not so many as twelve.

5862. Do you remember the circumstances under which the conversation took place between you and Dr. Hoggan ?—I do.

5863. Was it a casual conversation, or did he come to you for advice ?—It was a casual conversation.

5864. Can you give it to us as far as you remember it ? What led to it ?—He was elucidating some theory of respiration at that time as a student, and we had many arguments together regarding it, and it was at that time that I advised him to have more proof by using vivisection.

5865. He had not used vivisection, as far as you understood, up to that time; is that so ?—I am not aware of his having used vivisection up to that time.

5866. Now will you go on with the conversation as far as you remember it. Do you remember what led to your mentioning cats as animals that were not proper to be employed for the purpose ?—No, I do not; it was in the course of casual conversation. I mentioned that merely as an advice to him to use the most convenient animal to give him the least trouble.

5867. Were the experiments which he proposed to make, and which you advised him to carry out upon living animals, experiments which could have been made under anæsthetics without injuring the effect of the experiment ?—I cannot say.

5868. Was your conversation with reference to a particular class of experiments to be made for a particular purpose, or with reference to experiments generally on living animals ?—Experiments to be made for a particular purpose.

5869. And that is the only conversation which you recollect having had with him ?—That is the only conversation that I recollect having had with him.

5870. (*Mr. Huxley.*) Could you tell us in a few words what was the nature of the theory of respiration which was to be tested ?—The theory was that the forcing of the blood through the lungs by the heart had the power of expanding the lung itself.

A. J. Sinclair, M.D.

14 Dec. 1875.

5871. Independently of the action of the respiratory muscles?—Yes.

5872. Do you mean that the forcing of the blood into the lungs distended them?—I do.

5873. That is a purely mechanical problem?—A mechanical theory of respiration.

5874. And one which could be subjected to no test except that of actual experiment by vivisection?—I believe not.

5875. On the face of it you will agree with me, that it does not look very probable?—Not very probable.

5876. But still it might be possible, by appropriate experiments, to determine the matter of fact whether the lungs are enlarged in accordance with the systole of the heart or not. I say it might be possible, without, of course, admitting that it is likely?—It might be possible.

5877. And seeing that this was the only way of bringing the thing to a practical test, you recommended Dr. Hoggan to apply that practical test?—I did.

5878. You are very familiar, I presume, with the relations of professors and students in the University of Edinburgh?—Yes.

5879. Is it not the custom in Edinburgh for a professor, if he finds a young man who shows a disposition towards scientific inquiries, to encourage him to pursue those inquiries?—It is.

5880. In fact, a professor would think he was failing in his duty if he did not so encourage a young man who showed ability?—He would.

5881. And it often happens, does it not, that a young man who shows such capacity is encouraged by his teachers to embody the results of such research in his thesis?—He is.

5882. That is very commonly the case, is it not?—Very commonly.

5883. And when such theses are meritorious, especially when they contain the results of good original research, it is very common that medals are awarded for them, is it not?—It is so.

5884. It is a matter of common notoriety that that is the practice of the university?—That is the practice.

5885. Were you actually a teacher at the time that Dr. Hoggan applied to you?—I was a demonstrator of anatomy.

5886. And therefore a teacher?—Therefore a teacher.

5887. Were you demonstrator in the university?—I was demonstrator in the School of Medicine.

5888. Was Mr. Hoggan then a student?—He was a student at that time.

5889. And you stood to him in the relation of teacher to student?—I did.

5890. And in giving him that advice you were pursuing the course, I presume, that you would have pursued with regard to anybody who showed an aptitude for research?—Yes.

5891. You considered that you were simply doing your duty in that?—Yes.

5892. It was not from any general love of vivisection that you advised him to make these operations?—Not at all.

5893. (*Mr. Hutton.*) Is it the fact that cats are particularly difficult to handle under chloroform?—I cannot speak from experience as to that.

5894. We were told yesterday that they were particularly liable to the influence of chloroform; very easy to chloroform?—I cannot speak from experience on the subject.

5895. Might not Dr. Hoggan have fairly inferred from your suggestion that you were not thinking of the use of chloroform, but simply of vivisection without chloroform?—I cannot say so.

5896. As you made no reference to anæsthetics, and simply advised him not to use cats because they were difficult creatures to handle, did not that imply that they were not to be used under chloroform, or might it not so have implied to his apprehension?—I cannot answer how Dr. Hoggan would take it up. I certainly did not imply it myself.

5897. (*Mr. Huxley.*) As a matter of fact the preliminary operation of handling a strange cat before it is chloroformed is a difficult one, unless you know how to set about it, is it not?—It is. That is the reason why I advised him not to use cats.

5898. (*Mr. Hutton.*) Now would you at that time have thought him doing a wrong act if he had made these experiments on cats without using chloroform?—I would not.

5899. But the chloroform would not have interfered, I take it, with the particular action of the lungs that was to be inquired into, would it?—I do not think so, but I cannot say.

5900. When you spoke of your operations on frogs, you said that you were quite unable to give the number, which I can easily understand, but was it a large number or a small number of frogs that you had vivisected? Would you say, for instance, that they counted by dozens, or by scores, or by units?—Perhaps by units.

5901. You mean to say, of course, under dozens; you mean to say that certainly, if you have vivisected frogs, they have not been much above a dozen?—They have been more than a dozen.

5902. But not many dozens?—I cannot remember the number. I must have vivisected about 30 or 40 at least, perhaps more.

5903. Have you ever used anæsthetics with them?—No.

5904. Do you regard them as animals that do not suffer sufficient pain to need anæsthetics?—I do.

5905. And in regard to the experiments that you made with respect to the inhibitory action of the nerves, I think I understood you to say, did I not, that you did not use anæsthetics in some of those cases, simply because you thought that they might interfere with the results of the experiment?—I did think so.

5906. But that otherwise you certainly would have used them?—Yes, certainly.

5907. Why, then, do you say that you would not have condemned Dr. Hoggan if he had made these experiments on cats without attempting to anæsthetize them?—His desire was to elucidate a theory, and if anything had gone wrong in the experiment, he might have ascribed it to the action of the chloroform.

5908. You think that it might fairly have been ascribed to that? That it might really have interfered with the experiment?—He might have thought so.

5909. Do you think that the opinion in the University of Edinburgh generally at that time or now would be unfavourable to the making of experiments without anæsthetics, without any very special regard to whether or not the anæsthetic would interfere with the object of the experiment; I am speaking of painful experiments, of course?—I think anæsthetics would be used in every case that they could be used in.

5910. Do you think that the opinion of the university would strongly condemn a man in any case where he did not use anæsthetics, if it was clear that the anæsthetics would not interfere with the course of the experiment?—I do.

5911. (*Chairman.*) I understood you to object to inspection on the ground that you were not aware of any abuses which rendered inspection necessary; is that so?—Yes, that is the reason of my objection.

5912. But supposing that it were the object to prevent experiments being conducted, not by the persons whose humanity you have spoken of, but by a different sort of person altogether, of whose humanity no favourable account could be given, would you object on that supposition to the institution of inspection?—I would not; I would desire it.

5913. (*Lord Winmarleigh.*) Do you think that that is the general opinion of those who are engaged in the same practice as yourself?—I think so.

The witness withdrew.

P. D. Handyside, M.D., F.R.S.E.
14 Dec. 1875.

PETER DAVID HANDYSIDE, M.D., F.R.S.E., called in and examined.

5914. (*Chairman.*) You are teacher of anatomy in the Edinburgh School of Medicine ?—Yes, and examiner in anatomy, physiology, and surgery to the two Royal Colleges of Edinburgh, and during this year to the University of St. Andrews.

5915. And a consulting practitioner in medicine and surgery ?—Yes.

5916. And you have been acting and consulting surgeon to the Royal Infirmary of Edinburgh ?—Yes.

5917. And you have been for a great number of years, I think, a teacher ?—For 26 years. I was for 12 years teacher of anatomy and physiology, until the disjunction of physiology from anatomy in the Edinburgh School of Medicine. I then taught systematic, clinical, and operative surgery during two years of my service as acting surgeon. I have subsequently taught anatomy, human and comparative, for 12 years, including the current teaching year.

5918. That is your position as teacher at the present moment ?—Yes ; teaching anatomy regularly during six winter and three summer months.

5919. Have you had the opportunity of seeing some remarks made upon your name by Dr. Hoggan at question 3482, and so forth ?—I have. If I may be allowed to do so, I will make a remark on his answer to question 3471. Mr. Hoggan says, "I was strongly urged to try experiments by my teacher and by others, on a subject that had already been published. I refused to do so, and tried quite by myself" (although he was my demonstrator at the time this was unknown to me) "whether I could administer the anæsthetic and go through it. I found I could not do it, and therefore I refused to go further into the question until I had learned how vivisection was done." He never made any inquiry of me on these points. Then, at question 3472, he was asked "Am I to understand that you were advised by the lecturer whose lectures you attended to try experiments yourself ?" And his answer was, "I was advised by nearly every one of my friends to do so, and the lecturer, my own teacher, offered to associate himself with me, and put his own rooms at my disposal for the purpose." That I associated myself with him is not correct. I said to him that as he was my demonstrator of anatomy my rooms were at his disposal for any observations and experiments which, under my approval, he might make. That is quite the case ; but as for associating myself with him, I did not admit his theory. The word "associate" indicates that I took up his view, which I shall show afterwards not to be the case ; but as he was my demonstrator, he was associated with me in that sense.

5920. In popular language, you do not object to the term, but you object to it if it implies that you were identified with that particular view ?—Yes. At the end of question 3478, there is a quotation which evidently is meant to apply to me, and I probably did make use of those words, "You have laid it out beautifully in theory, but you must show by experiments how it is done ; you must try experiments on animals, and publish your theory along with those experiments." Now, I have no doubt that I said that, because I had confidence in Mr. Hoggan, as an elderly and intelligent student, and I told him, "It is impossible to establish your theory without experiments on the lower animals." Then, question 3480 is, "When this advice was given to you to try experiments, was it accompanied with any advice to subject the animals to as much anæsthesia as possible ?" He says, "There was no question of anæsthesia at all." My commentary upon that is that this was taken for granted. It was not spoken of, but it was taken for granted that anæsthetics should be used. With the exception of the experiments showing the circulation in the web of the frog's foot, he had never seen experiments by me. It is customary for me to put a dead dog upon the table for my introductory lecture ; but that dog I have either given prussic acid to, or pithed it, or given chloroform to it ; or I get from the Veterinary College a dead hound (often they have such animals which die under their care from disease). It seems the best introduction to a course of anatomy to lay a dissected animal on the table.

5921. The reason, as I understand you, why nothing was said to Dr. Hoggan about anæsthetics was, that it was taken for granted by you that no pain would be inflicted upon the animal in question that could be avoided ?—Clearly.

5922. And that he as your demonstrator knew that from the practice which he saw followed in your experiments ?—Yes.

5923. May I take this opportunity of asking you if you have been secretary of the Society for Prevention of Cruelty to Animals in Edinburgh ?—Yes, I had my share in originating that society in 1839, was the secretary for the first three years, and see nothing in vivisection inconsistent with the objects of that very humane society. The reasons I will give afterwards. Then, at question 3483, Mr. Hoggan is asked, "Is he a lecturer now ?" And his answer is, "Yes ; and he offered to associate himself with me in the whole theory." I reply to that that it is not so, I told him that I had no grounds from observation or experiment to think favourably of his theory. Then his answer proceeds, "and place his rooms at my disposal in order to elucidate the theory, or rather to illustrate it by means of experiments." This I did, but not the former ; that is to say, I did not offer to associate myself with him as favouring the theory.

5924. (*Mr. Huxley.*) I presume that you contemplated that Mr. Hoggan, then being a promising student, would probably make a good piece of original research, and for that purpose you let him have access to your rooms and the conveniences thereto attached ?—Yes.

5925. But it would be an error to suppose that you meant in any way to connect yourself with his work further than that ?—I had no intention of doing so.

5926. I am almost ashamed to ask you the question, but supposing that he had published a memoir on the subject, you had no intention of associating your name with it ?—No.

5927. Or in any way to take the credit of it ?—Not the slightest. I rather opposed it, and showed him that *à priori* it was unphilosophical, and that it was not based upon fact, and could not be established, as I conceived, by experiment ; but I gave him full liberty to throw light upon it by experiment ; it was my duty as a man of science to do so.

5928. (*Chairman.*) I think I have gathered from you that, as far as your long experience of teaching in Edinburgh goes, humane consideration for animals is always kept in view ?—Always.

5929. That in instituting experiments on animals, you, as far as possible, avoid experimenting upon them while they are living, or, that if you experiment upon them while they are living, then, if possible, it is under anæsthesia ?—Quite so.

3930. Now will you state what is the practice when there may be an experiment which must, if it is performed at all, be performed upon the living animal, and where anæsthetics would interfere with the experiment, is it the practice then to shorten the duration of any suffering as much as possible ?—As an illustration of that, I may say that when we show the action of the heart in a frog we always kill it beforehand, just instantly cut off its head, because the heart's action in a frog is as well shown after death as before. M. Onimus recently states that two hours after death he found the right auricle of the heart of a decapitated criminal beat spontaneously. After the lapse of five hours constant currents applied to the skin caused the contraction of the subjacent muscles. I may add that when a healthy dog's tail is cut off it will move for 20 minutes ; showing that irritability and vitality to that extent is not gone ; mobility remains but not sensibility. First, therefore, I say that the heart's action in a frog

P. D. Handyside, M.D., F.R.S.E.

14 Dec. 1875.

can be shown after death. And, secondly, if we want to show the action of the muscles, or to count the rapidity with which the nerve current moves in the frog, that also can be done after death.

5931. What you have mentioned you mention in confirmation of the statement that the sufferings of animals is an object always present to the mind of operators, as far as you know it, in Edinburgh ?—Yes.

5932. And that every effort is made to avoid suffering, and to mitigate and diminish suffering ?—Consistently with my knowledge that is always an object in view, and held stedfastly in view in performing experiments on the lower animals. I have an apparatus with me for the purpose of showing the circulation in the web of a frog's foot; very simple, being a slip of wood, a damp calico bag open at two parts, and a soft tape, and the animal suffers nothing. (*The witness produced it, and described it to the Commission.*) In order to show under the microscope the circulation in the web of a frog's foot, I place this instrument against the upright bar of the microscope. I then insert the frog in the bag, previously soaked in cold water, and its head projects here (*pointing to it*), and one limb at this point (*pointing to it*). I then bring this tape gently in this way (*describing it*), measuring the amount of pressure exerted upon it cautiously, because if I put too much pressure it will disturb the circulation; and so far, therefore, as these two stages are concerned there is no pain. Then the web is spread over this opening (*pointing to it*), and there are inserted four minikin pins, each $\frac{1}{8}$ of an inch in length, and so slender, yet conical, as not to draw blood. These transfix the web, which is very little sensitive as we believe; because the animal shows no repugnance in the shape of retraction or contraction of the part; after it is once in its whole body is at rest, and the web stretched out remains for about an hour under the microscope. The circulation otherwise is not interfered with, and its respiration is quite free during the period that the students are one by one looking through the microscope.

5933. (*Lord Winmarleigh*). You do not consider that a cruel experiment at all ?—No; and it is essential.

5934. And not attended with cruelty you think ?—Not attended with pain to the animal. I do believe that.

5935. Do I rightly collect from what you said that you can experiment on the nerves of a dog without inflicting pain ?—My remark applied to a frog at that time. We cut off its head. We always kill the frog before examining the heart, and then we may lay the heart out upon a bit of cold marble.

5936. But you alluded to cutting off the dog's tail, did you not, and said that you could operate upon the nerves without inflicting pain ?—My remark had reference to a large watch dog, the tail of which my elder brother wished shortened. After having sewed up the wound at the stump, and after the animal had run about, I watched the state of its detached tail, and found that till the expiry of 20 minutes, lying in the stone trough of a pump well, it was contracting and contracting, showing that the irritability and mobility remained under the contact of the irritation of cold for that period of time. It was the custom to dock ears and tails too, which I do consider unjustifiable and very cruel, as well as injurious to the animal afterwards. Still I make the remark as a physiological observation, and one which shows that there is no need for us to operate upon the nerves of a live frog when we wish to show the current through the nerves, because that is sufficiently shown from the irritability remaining after the animal's head, or the dog's tail, as the case may be, is cut off.

5937. You say that you have been secretary to the Royal Society for the Prevention of Cruelty to Animals ?—To the Scottish Society for the Prevention of Cruelty to Animals.

5938. Then I presume that you are not at all opposed to legislation upon the subject ?—Not at all opposed to legislation.

5939. You yourselves have recommended legislation on the subject, have you not ?—Though a director at present, I have not usually attended the meetings. However, if they have done so it is quite with my approval of certain legislation which I am prepared to suggest.

5940. What legislation would you suggest ?—I would suggest that a system of licensing would afford the general public "ample security that the practice of "vivisection is nowhere being carried on to any objectionable extent." And the operation of that might be, firstly, that certain students and registered practitioners wishing to conduct *original* experiments *only*, should be licensed; secondly, that teachers of anatomy, surgery, and physiology may be free to repeat such an essential experiment as that upon a frog's foot, showing it once to each of their classes; and also be free to conduct, *in private*, any original experiments under anæsthesia, where anæsthetics can properly be used. Then the mode of licensing should be twofold. Firstly, two laymen, such as justices of the peace, I think, should be required to say "We consider this party and these premises" (I would register both the individual and his premises) "a proper person to be intrusted with the performance of vivisection for original experiments, *or* "for teaching purposes, and a proper place for that "purpose." Secondly, to ensure that the experiments shall be original, there should be a certificate from a public teacher of anatomy, physiology, or surgery in a school of medicine, or in the medical faculty of a University, to testify that, "To my certain knowledge "A.B. is a fit and proper person to practise vivisection under the statutory regulations."

5941. You would have two justices of the peace in the first instance you say ?—Yes. I think laymen should be conjoined with a professional expert in order to allay public disquietude.

5942. But could two lay magistrates know the qualifications of the person ?—I think it well that they should represent the general public. Every teacher of anatomy must possess the Home Secretary's license, countersigned by two justices of the peace; and not only is the teacher licensed, but the place also where he means to practise anatomy.

5943. Does your plan include an inspector ?—Yes, three inspectors; one for Scotland, one for England, and one for Ireland.

5944. What class of men would you take the inspectors from ?—I think you require to have for inspector an experienced anatomist, practical surgeon, or physiologist. I think these are the only three who usually perform such experiments.

5945. What power would you give to the inspector ?—I would give him power to see that the Act is properly carried out. This power would run parallel to that of the inspector of anatomy. His duties are to see that there are no bodies dissected except those that are obtained according to the provisions of the Anatomy Act of 1832; that no one shall offend against the provisions of that Act, and that the Home Secretary be furnished quarterly (say, in this case, half-yearly,) with an official return.

5946. How many inspectors are there for the Anatomy Act ?—Three, one for each division of the kingdom.

5947. Is that found to be sufficient ?—Yes.

5948. Do you think that one inspector for each division of the kingdom would be sufficient for this purpose of licensing the practice of vivisection ?—Perfectly sufficient. Few indeed would apply for the license. In a great measure the excitement on this matter has no proper basis to rest upon. To supply vivisectionists adequately the number of animals required is comparatively few.

5949. But we have been told that the study of physiology is very much on the increase ?—Undoubtedly it is; and it is essential further to the advancement of medical science that physiological and toxological experiments should be performed. In the notes of my evidence before me I have stated

P. D. Handyside, M.D., F.R.S.E.

14 Dec. 1875.

that medical science is but in its infancy; and the past and future of medicine as a science in its infancy necessitates the licensed practice of vivisection.

5950. Do you know whether your views are in accordance with the views of the majority of the profession ?—I believe they are.

5951. Have you had much communication with the profession in London or Dublin ?—Not much, because we are so thoroughly at one on the subject that we have taken no share in these newspaper agitations, excepting that we concur in thinking that there is no good basis on which the objections taken to moderate vivisection rest. The ways in which we think that the consideration of the past and future of medicine as a science in its infancy points to the necessity of a licensed practice of vivisection are, first, by the discovery through experiments on animals of the properties of agents for relieving pain in man, such as chloroform ; secondly, the discovery of curative agents for the removal of disease; and, thirdly, the immediate rescue of human life from vitiated air, poisoning, and drowning. Experiments alone enable us to ascertain methods to be employed for this last-named juncture. For instance, Marshall Hall's methods and others' for resuscitation of man could only be substantiated through experiments on animals. Sir Astley Cooper's and Sir David Barry's experiments upon the circulation of the blood also call for mention. I say, in short, that experiment is the basis of medicine. The experiments of Mr. Syme on the periosteum of bone in living animals ; those of Sir Benjamin Brodie upon vegetable poisons applied to wounded surfaces of domestic animals ; and those of myself on the reproduction of cartilage, ligament, and nerve substance after excision of these ; on the portal circulation also ; and on the share that the lacteals, the lymphatics, and the veins respectively have in the absorption of poisons from the surfaces and interstices of the animal body;—all these have been admitted to be essential in their application to different phases of disease and accident in man. Further, with regard to colotomy, nephrotomy, and excision of the spleen, I may observe that we should not have been emboldened to perform these operations on man for the saving of his life without previous performance of them on the lower animals. I said that medical science is in its infancy, and I believe fully in vivisection; otherwise medicine, which is an inexact empirical, or tentative science, not like chemistry or mathematics, could not advance any further. The longer we live in the profession the more we see that we know very little; but we are getting exact knowledge, and I believe that is very much dependent on experiments on the lower animals done humanely and mercifully.

5952. I think I understood you to say that your opinion that it is desirable to put these experiments under some statutory regulation is an opinion which is shared in by the profession at Edinburgh ?—I have heard opinions in Edinburgh to that effect, but I have not spoken generally upon it. I believe it would be acceptable.

5953. (*Mr. Forster.*) Referring to the evidence of Dr. Hoggan, will you look at questions 3481 and 3484, in which he states, that in consequence of the kind of advice which, he says, you gave to try experiments, there was much private experimenting by the students ?—That is perfectly unknown to me. I am not aware of any case among my pupils of any such private experimenting by them as pupils; but I may give the name of Mr. Gilruth, who, after having passed physician and surgeon in 1865, has experimented. He became my pupil only in 1867–8, my assistant in 1868–9, and he performed his experiments between 1868 and 1873.

5954. If you will observe the exact form of the question at 3484. I asked Dr. Hoggan this question, " Then you give this as a fact, that you desire us to " take, upon your own personal knowledge, that at " the time that you were studying medicine at Edin- " burgh, it was common for the medical students to " try private experiments, and that with the know- " ledge and concurrence and approval of the lec- " turer ? " You in fact being the lecturer. And his answer is, " I do " ?—To that I answer, that it is not so, so far as I am concerned or have reason to know. Therefore I give a distinct denial to that statement included in the words, " it was common for the " medical students to try private experiments, and " that with the knowledge and concurrence and " approval of the lecturer." I do not believe any other teacher did such a thing, and I know that I myself never did.

5955. In the years 1871 and 1872 you were a lecturer, were you ?—Yes, as now on anatomy.

5956. Was there any other lecturer at that time ? —None connected solely with the Royal colleges. Mr. Turner was then as now in that capacity in the medical faculty of the University.

5957. And at that time, whenever anæsthetics could be used in any experiments, you yourself used to use them, did you not ?—I always did.

5958. (*Sir J. B. Karslake.*) For how many years have you been a lecturer having classes under you ?— This is my 26th year in teaching, 12 of which number were employed in lecturing on anatomy and physiology, 12 on anatomy, and two more (making the whole number of 26) on systematic, clinical, and operative surgery, in connexion with part of my term of office as acting surgeon to the Royal Infirmary.

5959. In the course of that number of years, have you ever recommended to students who were members of your class to practise these experiments on living animals in private ?—No.

5960. Or have you ever suggested it to them ?—No.

5961. And as far as your experience goes, have they done so ?—No. I am not aware of any, except what Dr. Sinclair has admitted in his evidence here to-day, that he had experimented, but when, is unknown to me. I did not recommend or suggest it to him.

5962. With regard to the question of the licence, as far as you yourself are concerned, and as far as you know the opinions of others in Edinburgh, would it be felt to be the least slur on the profession or on physiologists that they should act under the authority of a licence ?—I believe that some might not like it, but I think there is no ground for that feeling. Mr. Turner and I, for instance, are licensed as teachers of anatomy, and we are threatened with imprisonment for three months or a fine of 50*l.* if we depart from the regulations. Since we brook that, we could quite well brook having a licence to operate upon the lower animals, with a view to quiet the general public.

5963. Although you are under those regulations, they do not inspire any great terror in you, I gather ? —Not the slightest; and I should be very happy to see vivisection put under the provisions I have already suggested, to license the place and the man, just as under the Anatomy Act. There would be a parallelism between the two Acts, and a great affinity between them, to protect the practice of anatomy, and to regulate the practice of vivisection.

5964. (*Mr. Huxley.*) I asked Mr. Hoggan, on the occasion on which he appeared here, whether, when you gave him the advice which has been referred to, he had not been a medical student for three years, and he told me that he had been, and he stated that he had gone through two courses of anatomy; that was so also, was it not ?—It was.

5965. He had attained such an amount of proficiency in anatomy, that you had made him your demonstrator ?—Yes.

5966. I presume I may take it that you would not make an unskilful person, a clumsy person, a demonstrator ?—Never. I required a man of good talent as an anatomist. Dr. Sinclair, who has been examined here to-day, was my demonstrator for the two previous years, but he went away to a practice in England; Mr. Hoggan had been my assistant in my museum and anatomical researches, and I said to him, " You " can undertake this," and I found that he could do it uncommonly well, and that he satisfied all my pupils.

P. D. Handyside, M.D., F.R.S.E.

14 Dec. 1875.

5967. I may take it from you that the office of a demonstrator is one which requires considerable knowledge and skill in anatomy?—Yes.

5968. So that in giving this advice to Mr. Hoggan, you were not advising a raw student to begin vivisectional experiments?—Quite the contrary; I was advising a man in whom I had confidence.

5969. And as a matter of fact Mr. Hoggan would have had and would have needed no further instruction in anatomy?—And I believe got none; I am not aware of it.

5970. In reply to an inquiry of mine Mr. Hoggan said that he made medicine a sort of pastime. Under those circumstances you will understand that it did not occur to me to put to him a question which would elicit the statement which you have just made; so that we had not any information before us which led us to understand his exact position as an anatomist. But I now take from you that so far from its merely being a pastime, he was actually so accomplished in anatomy that you made him your demonstrator?—Yes; but he is so far accurate in this statement which he makes in answer to question 3496. "I had retired "from the service and made medicine a sort of "pastime;" he told me himself that he was a Royal Navy engineer on board ship for distillation of seawater at Annesley Bay during the Abyssinian war, as I understood him to say to me; and we frequently talked of it, for I asked him the process, and I found him a most intelligent man. He visited me in my house, and I had a good deal of communing with him at the museum. With regard to Mr. Hoggan's statement at question 3491, that he had been three years a student when I gave him the advice, I would remark that Mr. Hoggan was an elderly and distinguished student in whom I had more confidence as a demonstrator of anatomy than in many a young M.D. He had in fact raised himself from the position, as I understood him to say, of a working engineer on the Clyde, and thence went to India. He, as a navy engineer, showed great acuteness, conjoined with habits of steady and close application.

5971. I presume in your long experience as a teacher, it has often happened to you to have intelligent students coming for your advice in respect of views which they might entertain; and I suppose I may take it that you would not only give them freely such advice as you thought most appropriate in the particular case, but that you would regard it as your duty to give it them?—Unquestionably.

5972. I put to Mr. Hoggan this question at No. 3519. "Is it not within your knowledge that "the professors and teachers in the University of "Edinburgh think it their duty to encourage any "young man who shows a certain amount of scientific "aptitude, to carry out original research, and to "embody the original scientific research in the thesis "which he presents?" To that inquiry I got no direct answer. I will put the same question to you?—Clearly it is so.

5973. Is it not a matter of perfect notoriety, familiar to everybody who has ever been in the University?—And the School of Medicine in Edinburgh generally, comprising both the original school founded by the two Royal Colleges and the more recently formed Medical faculty of the University. It is uniformly the case. It is the duty of the teachers, and they do it.

5974. And I presume that if a student, of whose aptitude as an anatomist you had no great opinion, or whose knowledge you had reason to doubt, came to you and suggested that he should make a research involving difficult experiments, you would tell him that he had better learn anatomy first?—Clearly. I would not allow anybody not acquainted with the foundations of anatomy and physiology to venture upon such a course as experimenting on a living animal.

5975. May I ask further, whether it is not within your experience and knowledge true of persons engaged in physiological pursuits, that when the alternative arises in experimentation of performing experiments with anæsthetics or without them, the choice of anæsthetics is sure to be made, unless they should be in some way injurious to the experimentation?—That is always the case, and I am including myself in the answer.

5976. Did you ever meet with anybody who would deliberately say that he did not care to administer anæsthetics for the benefit of the animal, or for the prevention of pain in the animal experimented upon, but that he simply used them to save himself trouble?—I never met with such a monster.

5977. You know Edinburgh well, and you have known the life of medical students there for 25 years, if not more. Do you think that any man would dare say that in Edinburgh in medical society?—Certainly not. There is a remark which I should like to make on Mr. Hoggan's answer to question 3523, bearing on that point; he says, "I know that the question of "putting in a thesis is often spoken about with "a sneer." Now, as a public teacher of 26 years standing, I can state that I have never heard a thesis spoken about with a sneer. Then at No. 4022 Mr. Hoggan is asked this question, "I think you stated that "Dr. Handyside advised you to conduct this experi"mental inquiry, because you had stated to him that "you had new views upon respiration?", and he answers, "I had done so for a period of about two "medical years, and every other day I am sure I "had the same advice from Dr. Handyside." The true way to state that would have been that as occasion offered he had the same advice from me. I quite concur in his answer to question 4023, and in the quoted portion of his answer to 4026. The last question that has been sent to me is this, No. 4032, "I "only want to get out the facts clearly; and it results, "from what you have stated, that the recommenda"tion made to you, although there may have been "no explicit statement about anæsthetics one way "or the other, to perform these experiments, did not "necessarily imply that you were to perform experi"ments of a painful character?" His answer is, "There was the implication that the experiments "were of a painful character, or I would not have "given the answer that I did." The statement made in the question is true.

5978. (*Mr. Hutton.*) Did I rightly understand you that you had never advised any other student *in statu pupilari* to make these kinds of experiments except Dr. Hoggan?—Not to my knowledge. I do not believe that I ever advised students to make experiments, for these reasons, that I had not found them qualified, or they had not been engaged in investigations necessitating experiments.

5979. In regard to question 3479, "Do you think "that a similar advice was given to other students?" Dr. Hoggan's answer was, "I have no doubt of it "whatever, because several students have told me. "One told me, who is now dead, that he had per"formed 10 or 15 experiments on cats shortly before "then, and recommended me strongly, as what he "had seen was so very clear, to get cats and dogs and "examine the action of the various muscles in those "animals, that I had contended in my dissertation "had not the use that was assigned to them." With regard to that answer, you state that you would, as far as your experience goes, entirely deny the drift of it?—I never read question 3479 as having any application to me; if it has I quite deny it.

5980. You will observe that the question was, "Do "you think that a similar advice was given to other "students?" And the reply was, "I have no doubt "of it whatever"?—I did not read that as applying to me; it is too wild a thing to suppose it; but if meant to apply to me I give it a positive denial.

5981. I understood Dr. Hoggan to say that he was for two years your pupil, between 1869 and 1871, and that during the whole of that time he had the same kind of advice from you. At question 4022, Mr. Huxley asked him this question: "I think you stated that "Dr. Handyside advised you to conduct this experi"mental inquiry, because you had stated to him that

P. D. Handyside, M.D., F.R.S.E.

14 Dec. 1875.

" you had new views upon respiration?" And his answer is, "I had done so during two medical years, " and I constantly had the same advice from Dr. Han- " dyside." There I think you confirm his statement? —To Mr. Huxley's previous question 3491 "How " long had you been a student," Mr. Hoggan answers, "I may say three years." He had been my regular pupil during 1868–9, the summer 1869, also during 1869–70, and summer 1870. From the time that he had these views upon the respiratory muscles, I certainly, as occasion offered, encouraged him to perform experiments.

5982. Dr. Sinclair to-day dates that as 1869?—It is quite possible, because he was an ingenious man, and he was disallowing my explanation of the functions of the *serratus magnus* in conjunction with inspiration. I said to him at the very commencement, " *A priori* I think the argument is against you. It " is possible that you may be right, but you cannot " bring it out without experiments on living animals;" and he had liberty from me to perform certain experiments of a mechanical nature to prove on a dead human body how insignificant the heart's suction power is. He left off speaking to me because he found that I was so opposed to his theory; and it was discussed in the Medical Society, in the whole house, who, I understand, were not favourably disposed to it.

5983. In 1869 would not Dr. Hoggan have been a young student rather than an old one?—I was working at the time at the gorilla and chimpanzee, porpoise, potto, &c., and I found that, being neat-handed, he could assist me. He assisted me in my microscopic adjustments, was a good deal about me in the museum, and I gained confidence in his mechanical dexterity and his intelligence. He became, I think, an assistant in conducting a tutorial class in the first instance, then my assistant in the dissecting rooms during the summer and autumn of 1870, and from thence I promoted him to be my demonstrator at a nominal salary for winter session 1870–71, when his engagement came to a close and he left me for good; so that his answer to question 3485 can have no application to me. I found, when I could not get another diplomated demonstrator at the time that Dr. Sinclair left me in 1870, that I could trust Dr. Hoggan. I had at that time eight women attending my public lectures and dissecting room, and he gave most entire satisfaction to all the pupils in his demonstrations and dissections.

5984. Still, in 1869, he would have been young in his course?—Yes; perhaps so. At the time he was my demonstrator he had just completed his full course of anatomy. He got his certificates from me as a pupil afterwards. On his reminding me that he had not got his certificates of class attendance, I gave him these. I had employed him as a demonstrator for six months, and as such had reason to be decidedly satisfied with him.

5985. If, in 1869, he was advised to make these experiments on living animals, he was rather young for that purpose, was he not, as a medical student?—If you have confidence in a man, you can employ him very early if he shows intelligence, and if he shows that he is up in the knowledge of anatomy. But I am not aware at this moment that he ever performed a single experiment on an animal. I gave him the advice, but he never told me that he had ever tried the thing. I said, "To do anything, Mr. Hoggan, you must prove it by experiments."

5986. You have given very strong evidence as to the humane feeling towards animals in Edinburgh generally; do you mean that to apply to frogs also?—I do indeed.

5987. That frogs would not be operated upon, except under anæsthetics, where anæsthetics could properly be used?—I would rather employ anæsthetics upon frogs. I must admit I have not done so, because I have not put them to any pain in stretching the web, or for the purpose of showing the circulation.

5988. But in more severe experiments I mean?—I would always use anæsthetics in them.

5989. Do you think that that is the prevailing feeling in Edinburgh, because we have just had the contrary evidence?—To my knowledge anæsthetics are always given, and I have never seen experiments on frogs without the equivalent being employed, of cutting off their heads.

5990. (*Mr. Forster.*) And you have seen the experiments performed with anæsthetics on frogs, have you?—No, I have not. What I have seen at the Royal Society performed by the late Dr. Bennett and Dr. Rutherford together, when he was his assistant, were experiments on frogs when the head was previously cut off, and then currents of galvanism passed through and other experiments performed on them; but I have not seen the experiments referred to by Sir Alexander Grant in the return which is before you; I have myself not used anæsthetics with frogs, to show the circulation of the blood; but if I thought that these experiments gave pain I would give chloroform.

5991. (*Mr. Hutton.*) You have not performed any more severe experiments with it?—No; I have limited myself to anatomy chiefly, with the exception of 12 of the previous years that I taught physiology also.

5992. (*Chairman.*) What I understand you to say is that, in your opinion, a cold-blooded animal like the frog ought to be included among the animals which are to be anæsthetised if experiments in their nature painful are performed?—Clearly so; I certainly hold that.

5993. And I see in the return which has been sent to us by Sir Alexander Grant it is stated that 133 frogs got curari. Do you consider curari an anæsthetic?—I have no experience with curari.

5994. Is there anything else which you wish to say?—Firstly, I would simply refer to the results of my own experience as a student from 1825 to 1831 in operations on horses and dogs, upon the injection of air into the veins; ligature of the aorta and other vessels; upon the effects produced on domestic animals, by lactucarium, with the view to ascertain its curative properties on man; and upon the share that the different absorbent vessels respectively have in taking up noxious foreign matters. Secondly, as a teacher of anatomy, physiology, and surgery, I followed up my experimental researches on absorption. I also assisted the late Sir James Simpson in experiments on swine, and Mr. Spence in experiments, I believe, upon dogs. Thirdly, I had experience from 1837 till about the year 1854, as secretary of the Harveian Society, instituted in 1782 by Dr. Duncan, and one of its chief objects being to promote experimental research, and composed of such men as the late Drs. Alison, Rutherford, Huie, Sir James Simpson, and others, all tender-hearted and humane men, who were opposed to the practice of inhumanity towards animals. This society is instrumental in encouraging the production of such prize experimental essays as that upon lactucarium just alluded to, that of Dr. Madden of Torquay upon cutaneous absorption, and the essay of Dr. Mortimer Glover of Newcastle on compounds of bromine, and chlorine, including chloroform (to which last has been ascribed Sir James Simpson's employment of chloroform). These and other subsequent essays have elicited information of the greatest use for the relief of pain and suffering in man; for the prolongation of man's life in disease and old age; and for his extrication from the peril of sudden death. Fourthly, I have had experience as having been requested to undertake the office of honorary secretary to the Scottish Society for the Prevention of Cruelty to Animals in 1839; and having much sympathy with these animals, I felt that there was nothing inconsistent with this in my practising vivisection, but that it was justifiable in me to do so, seeing that there was no deliberate pain inflicted by me upon these animals. It was not willingly done; it was not uncompelled by duty; but it was my duty as a professional man to vivisect these animals, with which I had much sympathy, and quite justifiable; seeing it is only in that way that an empyrical inexact science like medicine can be advanced. Upon man himself antimony, aconite, and strychnine have been used experi-

P. D. Handyside, M.D., F.R.S.E.

14 Dec. 1875.

mentally with most dangerous results; and trials with the Calabar bean and other articles of the materia medica made on man, that properly ought to have been previously made on animals, have nearly cost us the lives of more than one eminent medical man. "How much is a man better than a sheep!" therefore we are at liberty to perform these needful experiments on the lower animals; *fiat experimentum in corpore vili:* and upon that principle "Ye are of more value "than many sparrows," I think it is quite justifiable for us so to operate. This we can do consistently with the most humane and merciful feelings towards the lower creation.

The witness withdrew.

Mr. William Williams called in and examined.

Mr. W. Williams.

5995. (*Chairman.*) You are the principal of the New Veterinary College at Edinburgh?—I am.

5996. You have had the opportunity, I think, of seeing some mention that has been made of your name before us by Mr. Mills?—I have.

5997. Have you any observation to make upon that evidence?—Simply that I know nothing about the operations referred to at Question 4949 in the statement "The principal, I believe, knew of it."

5998. Then in answer to what is said under head 4949, you say that you did not know of anything of the sort?—No.

5999. Do you believe that anything of the sort occurred?—I think so; I have heard something.

6000. Is it then, as we understand you now, an abuse that took place?—Certainly.

6001. And do you suppose that it was an isolated case of abuse, or are such abuses common in the Veterinary College at Edinburgh?—It is the only one that I have ever heard of.

6002. Have you made inquiry since you heard of this, to know whether any other such abuses have taken place?—I have.

6003. And what is the result of that inquiry?—This is the only instance that I can find.

6004. Are the regulations of the Veterinary College such that you might have expected that such an abuse would be brought to your knowledge?—It is a difficult matter to get students to tell upon one another.

6005. Then are we to suppose that in the Veterinary College at Edinburgh abuses of this kind might frequently take place?—Not frequently, certainly.

6006. Do you think that you might be able to make your regulations such as to prevent the possibility, or at any rate the likelihood, of anything of the kind occurring again?—I think so.

6007. Now in the answer to question 4955 it is said that the practice must have been "lasting at least for the last five years"?—That is untrue; because five years ago I was at the old college, and the space of the yard there was much more limited.

6008. Now is the whole story at all conformable to what is the practice at the Veterinary College at Edinburgh?—Certainly not.

6009. Do you purchase a horse for the purpose of dissection?—Yes.

6010. And then, before you kill him, permit experiments upon his living body to be performed?—Certainly not, with the exception of the experiment for the stone, which I perform myself.

6011. You perform an operation for the stone, not for the cure of the horse, as I understand it?—No; the horse is bought for dissection.

6012. And while he is still living you perform experimentally upon him an operation for the stone?—Yes; I do.

6013. And do you use any anæsthetic then?—Always.

6014. What anæsthetic?—Chloroform.

6015. Have you any other observation to make upon the statements of Mr. Mills which have been communicated to you?—He says here that the animals bought were dogs and cats; that is at 4927. I can safely say that I never performed an experiment upon a cat or a dog in my life myself, nor am I aware of any student having done so. I think I am in a position to state that, at least within the college, and within the knowledge of the college authorities, that no students ever perform on cats and dogs.

6016. (*Lord Winmarleigh.*) What is the nature of the building?—There is a large mansion house at the new college for the lectures and so on, and at one side I have some loose boxes and a dissecting room.

6017. Is there a yard?—There is a large space, and there is a paddock and a garden of about five acres of ground behind.

6018. Supposing that a horse was to be kept for experiments of this kind, do you think it could be done without your knowledge?—Certainly not; if I were at home I should know of it.

6019. Are you much from home?—I am a great deal from home. I have a large consulting practice in Scotland.

6020. You cannot state therefore whether this horse was brought into the college?—I have made inquiry, and the professor of anatomy tells me that he knows nothing about it.

6021. Is he always present?—Yes.

6022. How do you account for our being told that the horse had been there three days?—He might have been during the Christmas holidays. I cannot fix upon the time; I cannot make it out. But I understand that the horse had his tendons divided, and had had the nerve operation performed upon him in the paddock behind the building.

6023. And from your inquiries is it a fact that he was allowed to be there three days during the operation?—I cannot speak to that. I think it is hearsay evidence that Mr. Mills adduces.

6024. May I ask you what the rules of your college are? Is it ever allowed for students, or any other parties connected with the college, to bring in animals and to operate upon them without your knowledge?—No; except to bleed. They are allowed to bleed them.

6025. Then, if this has taken place it is contrary to the rules of your college?—Certainly.

6026. And how do you account for its never having come to your knowledge?—I never heard a word of it till I heard Mr. Mills' evidence, and I made inquiry, and it was stated to me by an old groom that he believes it was done.

6027. The result of your inquiry is that you do believe the thing was done?—Yes.

6028. And that Mr. Mills' evidence is correct as to the fact?—In so far. It is exaggerated, I think, as to the cruelty.

6029. What you do deny is that you knew anything about the matter?—Yes.

6030. The Commission may believe that the thing did take place?—Yes.

6031. And that Mr. Mills stated it with a little exaggeration?—Yes.

6032. (*Chairman.*) Do you confirm this (I am reading from Question 4957): "The subject that was "operated upon was a horse, and it was bought for "the purpose of dissecting. This animal was sub-"jected during a whole week to operations, such "as tenotomy and neurotomy, and various minor "operations"?—I believe that the operations were performed, but I do not think that the animal was allowed to live such a time as Mr. Mills states.

6033. "(*Q.*) Were those operations performed under "chloroform?—(*A.*) No; no chloroform whatever was "given. (*Q.*) Were no anæsthetics given?—(*A.*) "No; none whatever. (*Q.*) Were they painful "operations?—(*A.*) Very. The animal was cast by "means of hobbles. (*Q.*) And were they operations "chiefly on the nerves?—(*A.*) Nerves and tendons.

Mr. W. Williams.

14 Dec. 1875.

"And the animal was bled in different parts of the "body, for the purpose of the students simply de- "monstrating to each other things that could be "learnt in every-day practice." Now do you confirm the whole of that?—I believe that the nerves of the fore legs were divided, and I think the tendon of one leg; but I do not think anything further. The horse might have been bled. Students have liberty to bleed horses, to perform the operation, because I am of opinion that it entails no suffering on the animal, and that it is essential in every-day practice that they should be able to bleed expeditiously.

6034. Do you mean that if a horse is purchased by you and put into your paddock, or one of your boxes, the students can of their own motion, and without special sanction from you, go and perform tenotomy or neurotomy, or bleeding, whenever they please?—They can bleed with a phleme.

6035. As much as they like?—They can bleed once or twice. They generally bleed from the jugular.

6036. Do I rightly understand that if an animal is brought into your paddock and is intended to be killed, perhaps, a week hence—— ?—That is an exception to the rule. They are bought and killed the same day, as a rule.

6037. Supposing that the horse is to be killed the same day or the next day, may the students go and occupy themselves with bleeding him?—They can bleed him in the jugular vein.

6038. As many of them as like?—It generally belongs to one or two of the students. We never buy the subjects; the students themselves buy it.

6039. And is there no control at all on your part or the part of any of the professors as to the use made of an animal when he gets there?—Certainly; he is killed for dissection.

6040. Supposing a student buys a horse, and operates upon that horse, is there any control whatever exercised, in the sense of taking care that that horse is not improperly operated upon, cruelly operated upon?—Certainly, every care is taken of it; but they are allowed to bleed with a phleme. That is the only operation permitted.

6041. As often as they please?—They would not bleed him above once or twice. They may open both of the jugulars.

6042. (*Lord Winmarleigh.*) Supposing you had found out that this had taken place, what course should you have taken?—In all probability I should have expelled the student.

6043. Have you ever had occasion to expel a student?—Never.

6044. Can you of your own authority expel a student?—I can.

6045. (*Chairman.*) In your absence on journies in other parts of Scotland, is there any representative left by you to exercise discipline?—Yes; Mr Vaughan, Professor of Anatomy, Dr. Young, who lectures on anatomy, my clinical assistant, Mr. Johnston.

6046. And is any one of these charged especially with responsibility in regard to the humane treatment of any animals that may be there?—The clinica assistant, Mr. Johnston.

6047. Then if a student buys an animal for the purpose of dissection, he can, as I understand you, bleed him, if he likes, before, but he cannot do anything else until the animal has been killed?—No.

6048. If then tenotomy, or neurotomy, or any of these operations were performed, it was in direct violation of the rules?—Yes.

6049. And the person who in your absence was responsible for discipline, is the person to call upon for an explanation as to how it happened?—Yes.

6050. Have you called upon him for that explanation?—Yes; I asked Mr. Vaughan.

6051. Was Mr. Vaughan the person responsible at that time?—Yes.

6052. He had not heard at all of the case?—He had not.

6053. And do you suppose it is likely that such cases can happen without you, if you are there, or Mr. Vaughan, if he is the person responsible, knowing something about it?—This is the only case that I ever heard of.

6054. And the only case you believe to have happened?—Yes.

6055. Now, with regard to the treatment of subjects in the Veterinary College, am to I take it from you that their humane treatment is an object with you and with those who act with you?—Certainly.

6056. That when an experiment like that of lithotomy has to be performed upon them, anæsthetics are used first?—Certainly.

6057. And that the animal would be put out of his pain at the end of the experiment and before the anæsthetic had ceased to operate?—Yes, with the exception mentioned by Mr. Mills here (he seems in choosing the cases to have suited his own purpose), that this horse was allowed to live some hours after the operation was performed.

6058. Now was that done?—Yes, it was.

6059. And was there any good reason for that?—Yes.

6060. What was that reason?—It was stated that no horse could recover after having had chloroform, and it was done for the purpose of demonstrating to the students that the horse did regain its consciousness.

6061. Then it was a demonstrative experiment, not an experiment to ascertain any new truth, but to demonstrate what you knew before to the students?—It was to disprove a fallacy.

6062. It was not to satisfy you?—No; but there was a strong feeling amongst the students that session, in consequence of something which had been said by an old veterinary surgeon, that chloroform was always very injurious, and that no horse ever regained consciousness after its administration.

6063. Was the state of the horse during this 12 or 14 hours such as to make it a state of great agony?—Certainly not. The horse was eating.

6064. (*Mr. Forster.*) When was it that you discovered that this horse had been treated in the way that Mr. Mills says; I refer to the first horse mentioned, which was so treated in your absence?—By inquiry after I saw Mr. Mills's evidence.

6065. And what did you hear did really happen to it?—I heard that they had divided its tendons, and that they performed the nerve operation upon him.

6066. Did you hear how long he had been subjected to the operations?—No; it was only a kind of vague report from an old groom whom I had.

6067. You did not hear it from one of the students?—No.

6068. And could not he tell you the time that the horse was so treated?—No, he could not, but he was of an opinion it was during the Christmas vacation.

6069. Had he seen it so treated?—I do not know whether he had seen the operations, but he said that he believed that these operations had been performed.

6070. Will you be good enough to look at the answer to question 4997, in which Mr. Mills speaks of a second operation upon a living animal performed by yourself. The first we have already heard about, and that was a case of lithotomy. What was the fact with regard to this second case which you will find in 4997?—I destroyed one subject by blowing the jugular vein.

6071. You observe that it is stated that the animal was not put under chloroform; I suppose that is true, is it not?—Quite true.

6072. How quickly was it killed?—It died, I should think, in about 30 seconds.

6073. Just look at question 5003. "What was the "effect of the operation? (*A.*) The animal stag- "gered for a time and then regained his feet, and "then they pinned up the vessel and allowed the "animal to live for some time before he was destroyed?" —That is untrue. The horse fell, and after he fell, in order that he might be made use of for dissection, the

Mr. *W. Williams.*

14 Dec. 1875.

carotid artery was opened at once, and he immediately was bled.

6074. Then you remember the experiment ?—I do.

6075. And it is untrue that the animal was allowed to live any appreciable amount of time ?—Yes.

6076. (*Mr. Huxley.*) Your purpose in performing that experiment, I suppose, was to show the danger of allowing air to enter a vein in the course of bleeding ?—Yes, and also to demonstrate that it was by far the easiest method of destroying animals.

6077. It is a very swift method ?—Most swift.

6078. (*Mr. Forster.*) Now if you look at the evidence from questions 5034 to 5040, there is a statement there that you operated upon a horse bought for the purposes of dissection by some experiment on the tendons of the near fore leg. What have you to say about that ?—I remember nothing about that. I often perform tenotomy upon horses brought in for treatment.

6079. But do you put them under chloroform ?—No ; certainly not.

6080. Will you kindly give us a description of the operation ?—The tendons of the limb contract ; the horse walks upon his toe, and is unable to bring his heel to the ground, and for the purpose of enabling him to bring his heel to the ground the tendons are divided across under the skin. It is an exceedingly simple operation and almost painless.

6081. (*Mr. Huxley.*) It is performed on the human subject for a club foot ?—Yes.

6082. (*Mr. Forster.*) This mentions three cases in which experiments were performed on horses. Is it your custom to perform experiments on horses bought for the purposes of dissection ?—With the exception of operating for the stone, certainly not.

6083. But to some extent you do do so ?—I perform ithotomy.

6084. I have here before me the return which you made to the inquiries which have been sent by this Commission to many institutions. One of the questions is, "State what animals (including frogs) are " used either for original research or class demon-" stration, and give the number of each species"; the reply to which is, "Frogs only" ?—Yes ; that is written by Dr. Young. I never thought of the horse at the time, the thing really escaped my memory.

6085. In signing that you forgot it ?—Yes, I forgot entirely this operation for the stone.

6086. And you, I suppose, also forgot what had happened when you sent the next answer, in which it s said that the animals are always rendered unconscious ?—Yes.

6087. (*Sir J. B. Karslake.*) I believe in practice you never chloroform a horse for the purpose of firing him, do you ?—Well I do sometimes.

6088. Is the operation of giving anæsthetics to horses a difficult one ?—It is very difficult, a horse struggles very violently.

6089. And is it attended with any danger to the horse ?—It is attended with danger. We have to cast he horse before giving him chloroform, and he is n great danger of breaking his back during the struggles.

6090. During the time that the chloroform is being administered you mean ?—Yes.

6091. Now as compared with firing is tenotomy as painful an operation as firing ?—Oh dear no. I generally run a very small scalpel through the skin, underneath the tendons, then I put in a blunt knife hat divides the tendons, which have no sensibility whatever. The pain is simply in the division of the kin ; a mere prick in fact.

6092. Does the same observation apply to neuro-omy ?—No. In dividing the nerve there is con-iderable pain, just at the first cut.

6093. I suppose you have horses sent to you for he purpose of being cured, or rather to have pain lleviated by neurotomy ?—Yes.

6094. Do you then chloroform them ?—No, I do not.

6095. Is that a short operation ?—Very short. I have chloroformed for neurotomy, but I do not as a rule.

6096. With regard to the case that you have told us of, of tenotomy practised upon a horse that was brought in for dissection, was that the only instance, as far as you remember, of an operation being performed, with the exception of the operation for stone, upon animals sent in for dissection ?—You mean the operation by the students.

6097. No ; as I understood, you yourself are represented to have performed tenotomy upon an animal sent in for dissection ?—I do not remember ever performing tenotomy upon a subject.

6098. Do you remember the instance that was spoken to by Mr. Mills of your performing tenotomy ?—I often perform tenotomy upon animals sent in or cure.

6099. Was that upon a horse sent in for cure, or upon a horse sent in for the purposes of dissection ?—I do not remember ever having performed tenotomy on a horse sent in for the purposes of dissection.

6100. I think Mr. Mills said that he was two years under your tuition ?—He was a student for two years.

6101. Then you undertake to say that there was no horse sent in for dissection upon which tenotomy was performed before he was killed for dissection ?—Not by me.

6102. Or to your knowledge by any other person in the college ?—Not to my knowledge.

6103. Who else is there in the college that would have to perform these operations ?—My clinical assistant. As a rule I perform all the major operations myself, such as tenotomy, the division of the nerve, and firing.

6104. Those are operations on horses sent in for cure ?—Yes.

6105. Excluding those, is it the duty of your assistant to perform an operation, such as tenotomy, upon a horse sent in for dissection ?—Such a thing is never permitted.

6106. As far as you know, such a case never occurred during the time that Mr. Mills was there ?—I have no knowledge of it.

6107. You never performed it ?—No.

6108. With regard to the practice of students, is it a rare thing for a horse to be kept as long as a week before he is killed ?—Very rare.

6109. Is it since you saw this evidence that you made inquiries about the particular horse alleged to have had the operations of neurotomy and tenotomy performed upon it ?—Since I saw the evidence.

6110. Was the groom that you spoke to in your service at the time at the college ?—He was.

6111. As far as you know, was the clinical professor or any other professor conversant with the fact ?—No, they were not.

6112. As I understand, you never buy horses yourselves for the purposes of dissection ?—No.

6113. It is only when the students choose to club together, or as individuals, to buy horses, that they are bought ?—They are compelled to dissect so many subjects every session, and they buy them as they can. That has always been the rule in Edinburgh ; they must dissect so many subjects.

6114. And they must procure them themselves ?—Yes.

6115. And authority is given to the students, or to such of them as may choose to do so, to bleed the horse in each jugular vein before the horse is killed ?—Yes.

6116. And beyond that there is no permission given to them to perform any operation at all ?—None whatever.

6117 With regard to the operation for stone, is that an operation which can save a horse's life ?—Yes.

6118. And it is an operation which you are in the habit of performing for cure ?—Certainly ; it is a very rare operation, however.

6119. (*Chairman.*) Do you perform it under chloroform when it is for cure ?—Yes, I have ; but at the time of the first real operation I performed for the stone, chloroform was scarcely known.

6120. But would you perform it under chloroform? —Yes, certainly; the operation is much easier performed in that way.

6121. (*Sir J. B. Karslake.*) After the operation is performed for stone upon an animal, when it is designed to save his life, and the effect of the chloroform goes off, is the pain very considerable from the effect of the operation?—Yes, it is a painful operation; there is a wound made in tissues which are sensitive.

6122. And how long would the pain last severely? —Perhaps it would be severe for a couple of days; it would be as severe at least as the pain from any other wound.

6123. (*Chairman.*) But if the same sort of case arose in a human being, the practice would be, I presume, to use chloroform during the operation; but the human being would submit to the subsequent pain with any ordinary alleviations which might be administered?—Certainly.

6124. Then what I understand you to say is, that you treat a horse which you are operating upon for the cure of the stone exactly in the same way?—Decidedly. I do not believe that the subsequent pain is very great.

6125. (*Mr. Forster.*) I just want to call your attention, if you please, to questions 4970 down to 4977. Now you see that Mr. Mills says that animals were bought and operated upon for the purpose of exhibition and demonstration, and that it was not done at lectures, but was done during the dissecting hours, between 10 and 12, or in the afternoon; that these animals were horses and donkeys; that the operations were not frequently made, because of the difficulty of getting subjects, but that they were sometimes made by the students themselves, and sometimes by the professor. Now, do you know anything of those experiments?—With the exception of the operation for the stone, I know nothing about them.

6126. Do you believe that it was or was not true that there were those experiments made?—That it was not true.

6127. With the exception of the case for lithotomy, you believe that there were no such experiments?—Yes.

6128. Have you inquired in order to find out whether there were or were not?—Yes.

6129. And in what way have you satisfied yourself that these experiments were not made?—I have made inquiry from those about the place, and in fact I think I am in a position to state from my own personal knowledge that, with the exception of this case, which is admitted, no experiments beyond bleeding a horse have been performed within the college for a great number of years.

6130. (*Mr. Huxley.*) I perceive it is stated at question 4964, that the horse which we have had so much talk about was put into a paddock. Were there other horses with it?—No, there would be no horses in the paddock in the winter time.

6131. So that if a horse was put into that paddock, somebody must have seen it?—Yes.

6132. You were not there at the time?—I have no knowledge, except from hearsay, that the thing was done.

6133. You are, of course, perfectly familiar with all forms of veterinary terminology?—Yes.

6134. Will you tell me what this means; it is a document which is signed by Mr. Syme? "We, the " Court of Examiners for Scotland of the Royal Col- " lege of Veterinary Surgeons, desire to express our " opinion that the performance of operations on living " animals is altogether unnecessary and useless for " the purpose of causation." What does "causation" mean there?—I do not understand it; I think that must be a misprint.

6135. That document has been reproduced over and over again, and I have never been able to make anything of it; and you are unaware of any technical sense of the word?—I remember when that thing was drawn up, and I do not understand the word; I believe it must be a misprint.

6136. Can you tell us what was the ground of its being drawn up?—The experiments were performed at a French veterinary school at Alfort; it has reference to that I believe.

6137. What can be the meaning of this last phrase: "useless for the purpose of causation"?—I cannot tell; I think it is a misprint.

6138. From your knowledge of what took place on that occasion, can you express a confident belief that this protest arose out of the proceedings at Alfort, and not out of anything that took place in the three kingdoms?—I can. I remember seeing that in the "Scotsman" the following morning, and I asked those who had signed it what was the reason of it, and they said it had reference to the doings at Alfort.

6139. (*Mr. Forster.*) Do you recollect whether, when you first saw it, it had that phrase in about "causation"?—I think I do, now the thing is brought before me; but I can make inquiry.

6140. (*Mr. Hutton.*) In regard to the bleeding, do the students perform the bleeding of the jugular vein without superintendence? — The thing is so exceedingly trivial that we never thought of superintending that.

6141. If they were not superintended, is it not possible they might perform other and more painful operations without the knowledge of you and your lecturers?—I do not think so; besides I do not think they would do it.

6142. Why was the horse on which lithotomy was performed under chloroform kept so long as 12 or 14 hours? — He regained consciousness, and was destroyed the same evening. I lecture from 9 to 10. He was operated upon in the lecture room during that hour, and he had regained his consciousness before 10 o'clock. He was kept until the evening, and he ate his dinner and was quite well.

6143. I suppose the purpose you had in allowing him to regain consciousness, would have been answered if he had been destroyed in half an hour afterwards? —I do not think so. I wanted to encourage the administration of chloroform, and to overcome this prejudice which they had got hold of, that the horse did not recover from chloroform.

6144. With reference to Mr. Mills's statement that the students often performed operations in their private rooms on cats that they had snared in the streets, you are not able to state whether that happened or is likely to happen in future at all?—I have made inquiries, and I have been told by the persons I asked that they do not believe that any student with the exception of Mr. Mills ever did such a thing.

6145. Mr. Mills's statements were very explicit that others had joined with him?—They might have done so in their own lodgings, but certainly the thing is quite unknown.

6146. (*Chairman.*) Then I understand you, as the upshot of the whole business, to negative, as far as your knowledge and belief are concerned, the notion of cruelty as being practised upon animals by students in the Veterinary College at Edinburgh?—Certainly.

6147. And I understand you to say that if any such experiments are performed they are in violation of the rules?—Certainly.

6148. That you and the persons whom you have referred to in authority consider yourselves responsible for the observance of those rules in the sense of humanity?—Certainly.

6149. I have understood your answer that no experiments are performed, to cover the statement that no experiments are performed for the purpose of acquiring manual dexterity?—With the exception of bleeding.

6150. (*Mr. Hutton.*) During the Christmas holidays would the students be in residence, or would most of them be away?—They are mostly there.

6151. Then it is quite possible that the 70 or 80 students might have been engaged on this horse?—

Mr. W. Williams.

14 Dec. 1875.

At the new college we never have above 60; there might have been 40 or 50 at that time.

6152. And in reference to your lecturers, are they in residence in the Christmas holidays, or not?—Some are away; they do not come to the college; they do not live there.

6153. In fact there would be less authority there during the Christmas holidays than at other times?—Certainly.

6154. (*Chairman.*) Have you anything further to say?—I have nothing further to say.

The witness withdrew.

EDWARDS CRISP, M.D., called in and examined.

E. Crisp, M.D.

6155. (*Chairman.*) You are now in practice?—I am.

6156. You wrote I think to the secretary expressing your readiness to attend and give information to this Commission?—I did so.

6157. What was the particular point which you were desirous to lay before us?—I am rather a penitent upon this question. I have been a vivisector for some time. For several years I cut into animals, removing their spleens and the thyroid glands (the glands of the neck), and performed many other experiments; and as I advanced in age, and I hope in wisdom, I saw fit to alter many opinions that I had formed at an earlier period; and I have come to the conclusion that vivisection as practised, especially on the Continent, has not led to the good that its advocates believe. I think that there are many false inferences drawn, and one especially is as to the use of chloroform. It is assumed that because chloroform or any other anæsthetic is used, little pain is felt. Now I believe that that is a very false inference; for the pain is not during the operation, but the pain is after the operation in many cases. And there is another thing of which I speak especially from my own experience, that animals that are subjected to these operations are very much neglected, I speak of the frogs, I am ashamed to say now, and rabbits and other animals which I have killed which have been neglected. I think I attended, or should have attended to, these animals myself, but I am quite sure that in laboratories and places where they are left to attendants a vast amount of cruelty is practised. So that it is not the vivisection alone, not the cutting into these animals, that is so objectionable. Then as regards the lower animals I have taken the trouble, having paid great attention to the diseases of the lower animals, to look into the foreign journals and our English journals, to see the number of operations that are really required. I happened to be a candidate for the prize given by the Society for the Prevention of Cruelty to Animals, 1864, and that led me to pay more attention to this subject, and look up authorities, and investigate the matter more fully than I should otherwise have done. I found that (as probably all know here) eight students were at about the time when I made this investigation all cutting into a living horse at Alfort, Lyons, and Toulouse in France, and performed sometimes as many as 64 operations upon this poor animal, and as far as I could learn there was no positive good attending them, not the slightest in the world. The very few operations that I found can be practised on the lower animals with advantage were amputation of the penis, which does not require vivisection, lithotomy rarely performed and rarely successful, and a very few other operations. So that positively it appeared to me that all this cruelty was unnecessary, uncalled for, and that there was no good attending it. And then I have also come to the conclusion that, in a practical point of view, very little good has resulted from vivisection as regards the treatment of disease; and my impression is, that some restriction, if possible, should be put upon its frequent and useless employment. I think that with regard to our hospitals a committee should be formed at each hospital, who should regulate and control these matters, and that all useless experiments upon animals, oft repeated, should be done away with. I am not objecting to vivisection in some cases, because if I myself saw my way clearly, by operating upon any animal to benefit the human race, then notwithstanding any law that might be passed, even with the fear of imprisonment, I should do it; and therefore I think it is utterly impossible to suppress vivisection. But I think that this inquiry will do an immense deal of good by preventing the needless and useless operations in the cutting up of animals that have been performed.

6158. Your view is that operations of this kind cannot be altogether prohibited, but that they may be very much diminished in number?—Modified; I think so. May I be allowed to mention this, and I ought to mention it, although it may appear something like puffing myself. If I had been told when I recommenced my inquiries with regard to the structure and use of the spleen, and also the structure and use of the thyroid gland, that vivisection was not to be followed, I confess I should have said I would not investigate the matter at all; and one good resulting from my labours was this. Before I commenced my investigations it was stated that no valves existed in the splenic vein or abdominal veins of any animals; but I discovered from my investigations that they were very numerous in many animals. It is an important physiological fact. I confess I should have been stopped at once if I had been told that vivisection was not to be followed. I mention that as one very slight gain, but still it is worth naming, and so with the thyroid gland. I found that instead of its being the thyroid gland in a vast number of animals, there were two separate glands on each side of the neck. These are matters of no practical advantage as regards the treatment of disease, but still there is no doubt that in these investigations you are stimulated by emulation. I do not say that I had any desire to benefit my fellow creatures, but I was anxious to get a prize, and I wanted to beat other men, and I believe that is the prevailing feeling.

6159. (*Mr. Hutton.*) Will you tell us of any instance that you know of investigations of this kind which you think have been needless and very productive of pain to animals?—I will mention one especially that I am well acquainted with. I may mention, for the benefit of those who are not acquainted with anatomy, that there is a body which we call the supra-renal capsule; wrongly called supra-renal, and wrongly called capsule, because in many animals, as I discovered, it is quite away from the kidney, and in others not above the kidney. When Dr. Addison made a most important discovery with regard to these bodies, namely, that when they were diseased in a certain way death invariably followed, and the skin was discoloured in a peculiar manner, men naturally set to work to extirpate these little bodies, and to see the effect of this extirpation. Phillipeaux, Brown-Séquard, and a great many others did this. Dr. G. Harley, who obtained the prize at the Royal College of Surgeons for the best essay on the structure and use of these glands, 1858, came to a very erroneous conclusion about this disease which Addison had so well described, and which is now as well established as Bright's disease. He ignored the fact altogether, and then he came also to the conclusion, because the supra-renal capsules of a rat had been removed, that this rat after three years, when it became blind, died from old age, and he showed this to the Pathological Society,* of which I am a member. Not knowing at all that the removal

---

* The preparation is in the Museum of the Royal College of Surgeons, Lincoln's Inn Fields.

E. Crisp, M.D.

14 Dec. 1875.

of the capsules really shortened the animal's life, he came to the conclusion that the rat died at the end of three years from old age. Now the rat lives from 15 to 20 years. This is one instance which I mention; and I could name many others, more especially in regard to the cerebellum. The cerebellum has been sliced in all directions and in various ways, and various conclusions, as is well known, have been drawn; very opposite conclusions indeed. Although, as I said before, I should be very sorry to see vivisection done away with altogether, I believe its advocates have very much exaggerated the good resulting from it, and that some restriction should be put upon the practice. Unfortunately in this country we have almost as many teachers as students. I believe that the students will be about four to each teacher, scarcely that; and we have no central head, no faculty of medicine and surgery, no authority that could be consulted. If we had, perhaps the matter could be better dealt with.

6160. Can you tell me whether these operations of removing the supra-renal capsules are very painful ones ?—They must necessarily be painful.

6161. Were they done, or can they be done, under chloroform ?—Yes, they can be entirely so, and they were done under chloroform. But then you see, of course, operations upon the abdomen would produce a certain amount of inflammation afterwards, and the pain would not be during the operation but during the healing process, and this operation was almost invariably fatal. But I hope I may be allowed to say this, that I do not believe that any medical man has ever undertaken a vivisection without believing that some good would result from it. He has been mistaken—I think that I was sometimes; but I believe that all men who have undertaken these operations have done so under the impression that they might benefit their fellow creatures and promote the advancement of science. I do not think that any man would be so cruel as to do anything of the kind without he believed that he had a good motive.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock.

Wednesday, 15th December 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.

N. BAKER, Esq. Secretary.

Mr. J. M. Holt, M.P.

15 Dec. 1875.

Mr. JAMES MADEN HOLT, M.P., called in and examined.

6162. (*Chairman.*) I think you are a member of the committee of the society which has been formed under the name of the Society for the Total Abolition of Vivisection, are you not ?—I am.

6163. Are you well acquainted with the proceedings of the society ?—I am not.

6164. But you are one of the committee ?—I am one of the committee.

6165. How often does the committee meet ?—I am afraid I cannot throw much light upon the subject, for I have not attended a committee meeting in consequence of none being held in London.

6166. Where are they held ?—I think the committee meets very seldom; the members of the committee live at great distances from each other, and I do not think that they are able to come together often.

6167. Then it is rather desirable, is it not, that we should know what the authority of the proceedings of the society is. From whom does the secretary receive his authority ?—The communications which have passed between the members of the committee so far as I am concerned (I cannot speak for anything else) have been by post.

6168. Have you taken a considerable part in the management of the society ?—I have not.

6169. Do you know who has ?—I do not. I have communicated chiefly with Mr. William Harrison, and recently with Sir George Duckett. Would your Lordship allow me to say that I rather objected to join the committee, and wished to be placed as a vice-president or something of that sort in an irresponsible position; and when I did join the committee, I distinctly stated that I should be unable to take much part in its proceedings. I took the position provisionally, and have been endeavouring to get a reorganisation of the society, which has not yet been effected.

6170. The present organisation is not satisfactory to you ?—Not at all.

6171. In what respects is it unsatisfactory ?—Just in that, we do not meet regularly and in some central position which we can all easily reach.

6172. Have you paid much attention to the details of this subject which we are appointed to inquire into ? —I have not. It was my intention as soon as Parliament rose to devote myself to the subject. I was in bed with fever when Parliament rose, and I am sorry to say that subsequent weakness has defeated my intentions altogether.

6173. I am afraid we must consider your authority rather as expressing a strong sentiment of humanity than a detailed acquaintance with the subject which has been submitted to us ?—Any evidence which I can offer must be restricted to the opinion which I have formed, and the considerations which have led me to form it. That I am prepared to give.

6174. Will you be so good as to do so ?—I have made a few memoranda in order to make my statement more connected, that I might bring the subject before the Commission with less diffuseness, and if it be your wish I will put it before you in that form.

6175. If you please, we shall be much obliged to you ?—I share in common with others the pain and indignation with which the country has heard of the introduction into medical schools of the practice of vivisection in this country; and without indiscriminately condemning the whole of the medical profession, I cannot help agreeing with those who think that it inflicts a foul stain on the profession, that the governing bodies of those schools have not interfered earlier than this to prevent it, or to check it in some way or other. I would put before the Commission in the first place, the general objections which I entertain to vivisection, and then some special reasons why I prefer abolition to any attempts at restriction; and then I would enumerate a few consequences which I think will follow from the spread of the practice amongst us. In the first place I must go to the root of the whole thing. I think it is unjustifiable, because I regard it as an abuse of man's power over

Mr.
J. M. Holt,
M.P.

15 Dec. 1875.

the animals. I do not think, so far as I am able to judge, that it is contained in the original grant by God to man. The grant of power over the animals was not without restriction, because although man was to have the dominion over them, he was not permitted to use them for food. Therefore it is perfectly plain to me that we must not take the words of the grant in their very widest sense; that we must not take them without some limitation or restriction. The grant of the use of animals for food was subsequent to the deluge. Further I think that it is contrary to such indications as we have in scripture of God's will concerning our treatment of His creatures. I do not know that I need enumerate to the Commission, unless your Lordship asks me, the particular instances to which I refer, but I have them noted here; and further than that, it appears to me to be based on a principle which is altogether unsafe. That principle as it seems to me, is that for the purpose of scientific inquiry men may take what steps they choose without regard to the cost or the consequences; and that is a principle which I could not for one moment accept. I think also that it is contrary to the existing legislation which Parliament has sanctioned in this country. We have imposed a penalty on cruelty to animals, and we do not look upon motive at all. A man who overloads his donkey may say that he is doing it for the purpose of gaining a livelihood for his family; and there may be a good deal of truth in that plea;—the animal is required to work up to and beyond its legitimate strength in order to meet the requirements of the man's family; but in the interests of order and public good we impose a penalty on him; and I cannot see that there is any greater obligation upon us to provide means for the healing of our bodies than there is for the keeping of them alive in the ordinary daily course of life. Then so far as I have been able to acquaint myself with the subject, it seems to me that this practice is of very uncertain value; the faculty are not at all agreed upon the subject. I believe that the three instances upon which the supporters of vivisection rely to establish the fact that it is of service, are the discovery of the circulation of the blood by Harvey, the discovery of, I think it is, the double function of the nerves of the spinal cord, by Sir Charles Bell; and also the use of chloroform, by Sir James Simpson. But if I am correctly informed, so far as I have been able to investigate the subject, there is very great doubt as to whether vivisection really brought about any one of these discoveries. I have a few extracts here taken from a book entitled "Plea for Mercy to Animals," by Dr. James Macaulay, which I have relied upon a great deal in support of the opinion which I have formed; and I find at page 138 of that book an extract from the Honourable Robert Boyle's writings, to the effect that Harvey did not say that vivisection had enabled him to establish the theory of the circulation of the blood, but that anatomical research had brought it about, and that vivisection had been used for the purpose, as I understand it, of demonstrating to others that which he had arrived at by other means in the first instance. Then I understand that Sir Charles Bell distinctly denied that he had arrived at his results from vivisection. He discovered them by anatomical research, and he too had recourse to vivisection in order to overcome the prejudices of the profession;—the unwillingness of the profession to accept his discovery.

6176. (*Lord Winmarleigh.*) When does Sir Charles Bell say that?—Dr. Macaulay says, at page 140, "I have lately conversed on the subject with "Mr. Shaw, honorary surgeon of Middlesex Hospital, "Sir Charles Bell's friend and relative, and the able "editor and expositor of his published researches. "Mr. Shaw tells me that Sir Charles always spoke "of his discovery as due entirely to anatomical research." Then I understand from Dr. Macaulay's book that it is quite a mistake to suppose that Sir James Simpson discovered the use of chloroform by vivisection or by experiments on animals. Dr. Macaulay says, at page 138, "The fact is, the use of "chloroform was the result of an experiment, but "it was an experiment, and rather a perilous one, "tried by Sir James Simpson upon himself, and by "his assistant Dr. Keith." For that of course I have simply Dr. Macaulay's authority. Then I think that vivisection is further of very uncertain value, and I am supported in that by the opinion of Dr. Barclay on Muscular Motions, at page 298. He states,—that which I think one may easily conceive to be correct,—that the circumstances inseparable from vivisection must necessarily create a good deal of irritation of the parts and render the phenomena not altogether natural. Consequently in so far as they are not natural they must be misleading. I would submit also to the Commission that it is contrary to the tenor of our Christian civilization and dangerous to the moral tone of society. If we accustom the people of this country to hear of, to read of, and to think of cruelty in any form as allowable, the result will be that we shall encourage those savage unfeeling habits which it is the object of all civilized nations to repress; and I cannot help fearing that in the result there will be a reaction upon society in the form of making men more and more regardless of the feelings of their fellow men and their families. Then I submit further that it is hardening to students. It seems to me to have a tendency to destroy that tenderness of feeling which one wants to find in a medical man, and I think it leads him rather to look upon the patient whom he is attending as a case interesting to science, than as a fellow creature who is suffering and requires relief. For these reasons I have come to the conclusion, which I find expressed in the "Spectator" of the 15th of May of this year, that no alleged benefit which is derivable from vivisection can afford sufficient sanction for it. Of course these reasons go to the total abolition and not to the restriction of the practice. But in addition to these reasons I think there are some special reasons why the imposition of restrictions is undesirable. I for one want to know that medical men are not educated in a manner calculated to inspire distrust. It seems to me if I call in a medical man to attend a member of my family, and I know that he has been educated at a medical school where vivisection is practised, that instead of receiving him as I ought to do and placing full confidence in the recommendations which he may give to me, I shall be disposed to look upon everything with distrust and shall suspect he is likely to experiment on the patient instead of simply endeavouring to afford relief. I believe that the proposed mode of restriction,—that at any rate which has been suggested for the consideration of the country by the two bills which have been before Parliament,—is to be by an enforcement of the administration of anæsthetics. Now I do not think that satisfactory; because I do not see how you can with any certainty enforce the administration of an anæsthetic. There will be a very great amount of opportunity for evasion. I am told that there is a great deal of difficulty sometimes in administering an anæsthetic to an animal. Further I think it would be uncertain in its effects; you cannot be quite sure that the animal is insensible after the administration of the anæsthetic. And I would specially call the attention of the Commission to this. There is one alleged anæsthetic, curari, respecting which the profession is not at all agreed as to the effect which it has in destroying sensation in an animal. I contend that we can never be quite certain as to the particular effect which an anæsthetic may have upon an animal. There may be something beyond the reach of human ken with reference to any particular animal, so that an anæsthetic for some reason or other does not operate with it as it would ordinarily operate with other animals or with human beings. Again I urge that an anæsthetic is temporary in its operation; that it cannot be relied upon to last throughout the whole of the experiment; and that when the animal comes to consciousness it retains all the suffering which may remain as a consequence of the experiment which has been performed, and the anæsthetic will not have the effect of removing that. I am quite aware that that

Mr. J. M. Holt, M.P.

15 Dec. 1875.

objection might be met by ordering the animal to be killed immediately after the operation was performed; but still that would not quite meet this part of the objection which I raise, that the operation of the anæsthetic may cease to be effective before the experiment is at an end. It requires a scientific mind perhaps to deal with that question, but I feel a strong difficulty with reference to it. It is a serious objection in my mind, one upon which I should require a scientific explanation before I could dismiss it. Then I suppose, so far as I understand the matter, that in many cases the administration of the anæsthetic would be impossible, that is to say, that the effect of the experiment would be destroyed by it, and therefore restriction could not avail in that case. And I must also urge that even under anæsthetics, it would be very little less hardening to those who are to witness the experiment or to conduct the experiment, than when an animal is not subjected to anæsthetics. It is one of the misfortunes of the medical profession that the constant familiarity with suffering and with disease in its different forms and with the operations which must necessarily be performed, tends rather to blunt the feelings than otherwise. It may be very fortunate for the medical man that it is so, but it is not always fortunate for the patient. I repeat I think that restriction would be unreliable, and I do not see that even the most careful measures which might be adopted for the purpose of limiting the practise of vivisection would really remove from the public mind the objection which is felt by many persons towards it. On these grounds, finding that there is a very general consent on the part of medical men, not perhaps unanimous, that it is not desirable to continue vivisection for the purpose of demonstrations in hospital lectures, and also that considerable doubt is thrown on the value of those experiments which are conducted for the purpose of physiological research, and considering the difficulties attending the enforcement of restriction, I come to the conclusion that Parliament would do well to abolish the practice altogether,—to forbid it under heavy penalties. I would further call the attention of the Commission to the consequences which are likely to ensue if it prevails. I think they would be very disastrous both to the medical profession and to the country. I have already spoken of the effect of the practice being in my opinion hardening, and the effect of the principle being very objectionable, namely, that in the mind of the medical man the interests of science become of more importance than the immediate well-being of the patient; and I think the result must necessarily be (it is in my own case, and I know it is in the case of many others with whom I have conversed upon the subject) that there will not merely be a want of confidence in, but an absolute distrust of any medical man who was known to be favourable to vivisection, or to have employed it. And that will lead to a sort of exclusive dealing in the medical profession. I know at this moment that there are persons who will not consult a doctor until he has signed his name to a card saying that he objects to vivisection; and I do not think it is desirable that that should prevail throughout the country. Then I think it will lead to continued agitation, and probably that agitation might take the form of a sort of liberation society,—an endeavour to do away with the monopoly which at present medical men enjoy. There is a good deal of feeling in some parts of the country, and in the north of England especially, on the question of vaccination, and I think that the whole of these things will be mixed up together, and that we shall find an agitation prevail which may perhaps make itself felt on the hustings with reference to the exclusive privileges which the medical profession enjoy in this country. I do not know that that would be at all desirable. I think I have now gone through the memoranda that I have made. The conclusion at which I have arrived is that with which I commenced, that abolition is the thing which would be most satisfactory to my own mind, and I believe to the minds of a very large number of persons in this country; and I do not think, even if it were established that certain benefits could be obtained by means of vivisection, that any humane person would consent to be healed on those terms.

6177. Do you belong as well to the Society for the Prevention of Cruelty to Animals as to the society on behalf of which you now appear?—I am not an annual subscriber; I have subscribed to it.

6178. What was the cause of your society being instituted? Was there any other cause than that which you have just assigned, or was it that there was any dissatisfaction on the part of a particular portion of the public with the proceedings of the society already in operation for preventing cruelty to animals?—I believe it was felt that the Society for the Prevention of Cruelty was somewhat slack in its movements upon this question, and that it was desirable to take some steps which should bring public opinion more directly to bear upon vivisection.

6179. Since the existence of your society has it been mainly supported by the public?—Yes; I think it has been supported to a large extent by the public.

6180. Could you tell us about the number of subscribers at the present moment?—No, I am afraid I could not. I must again say to your Lordship that the fact of my having been so poorly has prevented me from taking any part in the matter, or from really acquiring the information on the subject which I had relied on the vacation to work up.

6181. But you believe that you are generally supported by the public?—I believe that we are very largely supported.

6182. That the object of the society is supported by a great body of the public?—I do think so.

6183. The Society for the Prevention of Cruelty to Animals, I believe, has a very large support throughout the country?—I believe so.

6184–5. Do you think it is greater than that which your society receives?—The Prevention of Cruelty Society has been established a much longer time and it has therefore a much greater support, I could not say whether it has a greater support than we have on this particular question.

6186. Are you aware that the Society for the Prevention of Cruelty to Animals sanctioned a Bill in Parliament by which, under certain severe restrictions, vivisection is tolerated?—Yes.

6187. That that society, established for the prevention of cruelty to animals, do recognise the necessity of vivisection to a certain extent?—I am aware that they have not felt themselves prepared to go in for abolition.

6188. That they have approved a bill in which this is inserted,—"That no person shall perform or cause "to be performed, or take part in performing, any "vivisection upon any animal without having first of "all subjected such animal to the influence of an anæs"thetic so as to render it wholly insensible to pain." And then the next section provides,—"That no person "who shall perform or cause to be performed, or take "part in performing, any vivisection upon an animal "so subjected as aforesaid shall omit to destroy such "animal before the effect of the anæsthetic ceases." That you disapprove; you go much beyond that?—Yes, that I disapprove.

6189. Is your society, then, against the infliction of pain of any kind upon animals?—Unjustifiable pain, unnecessary pain.

6190. Supposing that some of the facts which you have stated to this Commission were disproved to the satisfaction of this Commission, and in their belief to the satisfaction of the public, you would not persist then, I presume, in the position which you have laid down with regard to vivisection in its full entirety, would you? Supposing, for instance, that with regard to what you say about anæsthetics, it can be proved that without inflicting any pain on the animal, you could get some important result from the vivisection, you would then not object to it, would you?—I am afraid

Mr. J. M. Holt, M.P.

15 Dec. 1875.

I should, because I do not see how we are to secure the certain administration of the anæsthetic.

6191. But I say supposing that it was proved to the satisfaction of this Commission, and as we believe to the satisfaction of the public, that it can be conducted without pain being inflicted, would you object to vivisection under certain restrictions?—Yes, because I should fear that even though it can be, it would not be conducted without pain.

6192. We have had the evidence of the first medical men, and we must base our report upon that evidence?—I should not trust vivisectors. I think I understand your Lordship's position, that it may be established that it can be done without the infliction of pain; but I should query whether it would be done.

6193. You stated just now that you thought there were a great number of the public, I think you said, that would not submit themselves to a medical man who practised vivisection, from want of confidence in him?—Yes.

6194. Now should you be surprised if I were to tell you that we have examined men of the greatest eminence, Sir William Gull, Sir James Paget, and the first medical men in London, and that they have been in the practice of vivisection, and yet retained more confidence than the great body of the medical men of England?—I feel that the result will be, when it is known, that a great many persons will not consult them again.

6195. Do you think that would be the case with the great body of the public?—I cannot say about the great body of the public; those with whom I have come in contact feel very strongly upon the subject.

6196. You stated that you objected to the introduction of vivisection into England. Did you make that observation under the belief that it is a recent introduction?—Its introduction into the medical schools. I understand that for the purposes of demonstration it is perfectly modern; altogether modern so far as I am informed. I am quite aware that it existed before that.

6197. Now supposing that it should be the opinion of this Commission that vivisection might be permitted under certain severe restrictions, what would be the restrictions (waiving your own individual opinions on the matter for the present) which you would wish to impose upon it?—I have great difficulty in answering that question.

6198. You think that no restriction would do?—I am not prepared to recommend any restriction at this moment.

6199. Can you suggest to yourself any pain inflicted upon animals for the purpose of human food, for the good of the community, and which has been inflicted from the earliest ages, which would come under the operation of your society? Can you suggest to yourself any operations performed upon animals from the earliest ages in this country, and of everyday occurrence, which come under your objection to treating animals with cruelty?—Yes, I can; I can think of several.

6200. Would you abolish all those?—I think that would require some consideration. With regard to the last question which your Lordship put to me, I should like to add that I am contending against the infliction of unnecessary pain, and I contend that this is unnecessary pain. I should not perhaps contend that pain inflicted in other ways for other purposes was unnecessary; but each case must stand upon its own merits.

6201. Then if it should be proved that the pain was necessary you would not object, is that so?—If I were satisfied that the pain was necessary. Your Lordship will pardon me for observing that I do not mean to say that what will satisfy another person would satisfy me.

6202. May I ask you, could you in the course of to-day or to-morrow furnish the Commission with a list of your subscribers and of the state of the subscriptions to the society since its origin?—I am afraid that I could not do that to-morrow, because I should have to communicate with Mr. Jesse, and I suppose it would take longer time than that.

6203. Do you intend in the re-organization of your society to insist upon more constant meetings and more constant consultation amongst all the members?—Yes, I intend to insist upon the appointment of an executive committee that shall take the active control, and that the names of those gentlemen who cannot attend regularly, or who do not wish to be on the executive committee, should be appended as ornamental vice-presidents or patrons or anything they choose. I have quite made up my mind that I shall retire from the committee altogether unless some such changes are made.

6204. (*Mr. Forster.*) Taking your late answer to Lord Winmarleigh, I think I understood that answer to mean that supposing you were convinced that vivisectional experiments under regulation and restriction were necessary in order to enable the science of medicine to arrive at that point that life could be better saved, you would then admit of it?—I take the ground that it is unjustifiable in any case, and I do not think that any amount of argument could convince me that it was right,—that it was allowable.

6205. I certainly gathered that to be your opinion from your earlier answers; but in the recent answer that was given, the qualification that you made was this, as I understood; you said you would admit of pain to animals in cases of necessity?—I did not mean to say that. What I wished to say,—what I was contending for was, that there should be no unnecessary pain inflicted upon animals. That was in reply to a question which Lord Winmarleigh had put to me with reference to certain operations in agriculture; and what I meant in amending my reply to that question was to let it be clearly understood by the Commission that whilst I was opposing in this instance the infliction of pain upon animals altogether, I did not think that the infliction of pain upon animals was a thing which in itself I should oppose if I were satisfied it was necessary.

6206. But the point on which I wish to obtain your opinion is this, whether you base your opposition to all vivisection upon the ground that the pain given is unjustifiable, or upon the ground that you consider it unnecessary?—I base it upon the ground that it is unjustifiable.

6207. Then why would you say that the pain given by vivisection is unjustifiable, independent of the question of necessity, and at the same time admit that pain given in other ways is justifiable upon the ground of necessity?—Simply because the one seems to me to be within the grant of the animals to man, and the other not. If I may put it in this form, I would say, for instance, that where the use of an animal for the purpose of serving man's necessities requires that the animal should be corrected in a manner which causes the infliction of pain upon it, I conceive that man is perfectly justified in training the animal and in making use of correction for the purpose of training it to serve him.

6208. And you do not think that this power that you suppose was given to man over the animals would apply to making use of them for the preservation of human life by the assistance of science?—Not in the form which it has taken, certainly.

6209. Not even supposing that the pain given to one animal, or say to a score of animals, might be the means of enabling a discovery to be made which might save thousands of human lives?—I am not aware that that is so.

6210. But you are aware that there are many eminent men of science who would state that that has been the case?—I am aware that that is the contention of certain persons.

6211. And I should rather gather from your previous answer, in which you stated that all vivisection was unjustifiable, that even supposing it was proved that the pain given to an animal might be the means of a discovery which might save thousands of human lives, you would consider that such pain was not included in the dominion that was granted to man over animals ?—I should.

6212. I suppose you do not consider that any pain inflicted for the purposes of experiment is included in the power given to man over animals ?—I think that animals may be taken and killed for food.

6213. But you do imagine that they might be killed for the purposes of sport in any way ?—If by that you mean for the amusement of man, I would say certainly not.

6214. You would think that all destruction of animals, in so far as it was done for amusement and not for the purpose of obtaining food, was unjustifiable ?—Well, I am not a sportsman and I could not be a sportsman on the very ground that I should not feel justified in amusing myself at the cost of animal suffering.

6215. Do you think that this opinion is held generally by the members of your society in regard to sport ?—I think they make a distinction.

6216. A distinction in what way ?—They think that the question of the pain inflicted by sportsmen is outside this question.

6217. But do you think that the general number of the supporters of your society, while they are so strongly opposed to vivisection, share with you your opinion about sport ?—That I could not say.

6218. You have no opinion upon that matter ?—No ;—I am not prepared to say that they do.

6219. I suppose you would consider that in so far as any destruction of an animal in sport was not the quickest destruction of the animal that could be made for the purposes of food, it would be unjustifiable ?—I see a difficulty in judging the conduct of other persons. I could not myself take pleasure in taking the life of an animal, but I can quite understand that where the life of an animal is to be taken by the use of firearms, for instance, there must be a certain amount of suffering inflicted which cannot be avoided.

6220. I will put before you two cases of pain inflicted upon an animal ; one the case of pain inflicted by a man of science, with the hope, and in his belief the reasonable hope, of a discovery which would greatly alleviate human suffering and save human life ; the other, the case of pain inflicted by a person for the purpose of amusement, the pain consisting in subjecting the animal to a longer and more painful death than it would otherwise undergo for the purpose of food. Would you think that the first was more unjustifiable than the second ?—I should think that as regards the characters of the individuals, the first was more justifiable than the second, that is to say, I should look with less abhorence,—I do not know whether to use that strong word, I will say with less aversion,—upon the character of the man who was acting with the desire to benefit his fellows than I should upon the character of the man who selfishly was amusing himself at the cost of animal suffering.

6221. But with regard to legislation, which of the two cases do you think it would be more incumbent upon the legislature to pass a law for ?—I do not see how we could pass a law with reference to sporting, because it is the taking of animal life for food. It is simply a question of the mode of taking it, and I do not quite know how you could deal with that.

6222. (*Mr. Hutton.*) Fox-hunting is not a case of taking animal life for food ?—Fox-hunting would scarcely come under that.

6223. (*Sir J. B. Karslake.*) When was the Society for the Abolition of Vivisection actually formed ?—I joined it in March of this year. I cannot tell you when it was actually formed, for I do not remember when the first advertisement appeared.

6224. Was it formed by advertisement,—in consequence of advertisement ?—I can only say what happened with reference to myself. I joined it in consequence of seeing an advertisement in the paper.

6225. Is there any office in town ?—I am not aware of any. That is one of the things that I have been seeking to establish.

6226. I mean who would be the person to communicate with if one wanted to join the society ?—Mr. Jesse.

6227. Are there any documents published by the society, or by an authorised body of the society, such as the Committee, stating what the objects of the society are ?—There is a sort of programme, a general prospectus of the objects of the society, which has been published.

6228. Since you have been a member has there been any meeting of the members of the society to discuss the question as to how far evidence, so far as it could be obtained from books, proves the necessity for vivisection ?—Of the members, no. I know of none.

6229. Then, as far as you know, each individual member of the society entertains his own opinions from different premisses and upon different grounds ?—I suppose they concur in the general objects, but may not agree in all details. On that I can say nothing.

6230. But I may understand that there has been no meeting, so that the general views of the society, and the authorities on which they are supported, should be made known to the members of the society generally ?—No ; there has been no general meeting of members.

6231. Nor even of the committee ?—I have not attended any.

6232. And so far as you know there has been none ?—So far as I know.

6233. Have you any paid officers at all for the purposes of the society ?—No.

6234. None whatever ?—None whatever. I do not know at this moment. Mr. Jesse may have a clerk who assists him ; that I cannot tell. It was discussed when two of the committee were in town during the summer ; but of that I do not know anything with certainty. There may be a clerk employed by Mr. Jesse.

6235. That is to say, merely for the purpose of correspondence ?—Yes.

6236. But you have no officers in town for the purpose of ascertaining the extent to which vivisection goes on, or the places at which it is carried on ?—No.

6237. You have said that there has been no meeting of the committee, so far as you know. Suppose a communication appears in the papers which it is necessary to answer, do the committee take upon themselves to direct what answer should be given ?—I think those communications which have appeared hitherto have been matters in which Mr. Jesse has been personally concerned ; and I think the letters written have been more personal letters than letters of the committee.

6238. As far as you know, no committee meeting has ever taken place for the purpose of determining the answer to be given to any correspondence that has appeared affecting the society ?—No.

6239. That would devolve upon Mr. Jesse to determine ? He would be entitled to answer it in any way he thought proper ?—Yes.

6240. And to use the name of the committee as his authority for so answering ?—Well, I should not approve of that.

6241. (*Lord Winmarleigh.*) I think you said that you could, if we gave you time, furnish us with a list of the members of the society, and its funds, the object we have being of course to ascertain what is the amount of public support that your society has got ?—I have no doubt I can. I have not got it myself, but I will write down for it. I will get it as quickly as possible.

6242. (*Sir J. B. Karslake.*) May I take it that you have given us the grounds upon which you have come to the conclusion that vivisection ought to be abolished altogether ?—I think I have given them shortly but pretty fully.

6243. As far as they have occurred to your mind up to the present moment ?—Yes.

6244. You say that you have not had the oppor-

Mr.
J. M. Holt,
M.P.

15 Dec. 1875.

tunity of studying the pros and cons of the question as fully as you could have wished?—By no means. I meant to devote the vacation to the subject, but have been prevented by illness.

6245. I think you said that one of your objections to vivisection was that in your judgment it hardens the practitioner?—That is my fear.

6246. Do you yourself object to receiving advice from a practitioner who avows that he is friendly to vivisection?—I should object to put myself in his power.

6247. Would you carry it to this extent, that if he told you that in the disease from which you might be suffering it would be impossible to cure you without drawing largely upon the knowledge which he had obtained from works treating on vivisection, you would object to receive him then?— I think I should.

6248. If he told you that without the knowledge that he had acquired from those works it would be impossible for him to effect a cure, or hope to do so, you would reject his services?—I do say that I would reject his services because he had obtained his information in a manner I did not approve, if that is the meaning of the question.

6249. You would object to a man who had actually killed an animal for the purpose of research; would you also object to employ a medical man who avowed that the only knowledge he had as to the treating of the disease was derived from works which described operations upon animals which enabled him to judge how to treat your disease?—I feel a difficulty in answering the question. I do not know quite how it would come to my knowledge how he had acquired the information.

6250. I will assume that he told you so. As I understand many persons to your knowledge require, before they employ a medical man, that he should sign a statement that he does not approve of vivisection. Supposing you asked this gentleman whether he approved of vivisection, and being an honest man he said, "I do not approve of it or disapprove of it, but " I cannot treat your disease without drawing upon the " knowledge which I have obtained of the disease from " having read accounts of operations performed on " animals?"—I do not think that the manner in which his knowledge had been acquired—the source from which he gained his information—would affect my conduct in the matter.

6251. Then you would not think it objectionable for a man to study books treating on vivisection and the results obtained from vivisection, but you would object to a man who had actually vivisected an animal or performed an operation on a living animal?—I should think that the effect of studying such books was only a little removed, though it is removed, from the hardening effect of vivisection itself, and I would object to education either of the one kind or of the other.

6252. You would then think it preferable that human beings should suffer and die because the medical profession ought not to obtain that knowledge which they are supposed to obtain from books?—I would adhere to what I said just now, quoting it from the "Spectator" of 15 May last, that no alleged benefit can afford sufficient sanction for the practice.

6253. I am putting this question to you. Supposing that is wrong; supposing it can be proved to demonstration almost, or to the satisfaction of any reasonable men, that there are many most advantageous results which have been obtained from vivisection, and which could only be obtained by that means, would you then object to be treated by a man who was about to treat you by means of knowledge which he obtained from operations on animals?—I should not like it.

6254. If you are giving your views to the Commission upon the assumption that no good has been obtained from vivisection I will not trouble you further, but assuming this case that by operations performed on a dozen animals you could save the lives of many thousands of animals, would you object to those operations being performed?—I do not see that they are justifiable.

6255. Then your objection, as far as that is concerned, is, that man has no authority over animals to inflict pain of that sort, even for the purpose of saving, it may be, all the flocks and herds in the country?—That is putting it in an extreme form.

6256. It is a test you know?—I feel great doubt about it.

6257. I will put it in this form. Supposing that the sheep were being affected most fearfully with the small-pox, and that by the destruction of a few sheep you were able to stop the progress of the disease by the scientific results obtained by that means, would you then object to a few sheep being sacrificed, and that without pain, or with as little pain as could possibly be inflicted upon them under the circumstances?—I think each case would require to be dealt with on its own merits. As a general rule, I regard it as unjustifiable.

6258. Now let me ask you a little further, if you please, upon that. You will admit, of course, that for the purpose of curing animals or attempting to cure animals pain may be inflicted?—Surgical operations? Quite so.

6259. Now supposing a person were to believe that by an application of a new, and it may be a more painful blister than that which has formerly been applied, a better cure can be effected, would you object to that excess of pain being inflicted upon the animal?—No; not for the curing of disease.

6260. Supposing that the animal that was actually diseased was a valuable animal, whose life you wished to save, and that in lieu of using that animal you were to use an animal which was in the last stage of disease from other causes, and which was to be killed immediately after the effects of the operation were observed, would you think it unjustifiable to use the animal which I have described last for the purpose of ascertaining what the effect of blistering would be?—I think I should.

6261. (*Mr. Huxley.*) I happen to have been rather familiar with the organization of societies, and I beg to put to you two or three questions for the purpose of ascertaining whether within your knowledge the Abolition Society has been raised in the customary way. I understand that you have been a member of it nearly from its foundation?—From March.

6262. When was it founded?—That I am not able accurately to tell you.

6263. Do you know by whose authority the president or chairman was appointed?—No; I do not.

6264. Or the committee?—No. The committee I supposed had been formed of gentlemen who consented to act in that capacity.

6265. I think I understood you to say that so far as your knowledge goes there never has been anything answering to what you could call a general meeting of the society, either at its first formation or at any other time?—Not within my knowledge.

6266. Did you receive a communication on the subject of the formation of the society from Mr. Jesse?—In the first instance I saw an advertisement in the paper.

6267. The society is in possession of some considerable funds, I think?—I daresay.

6268. Has any treasurer been appointed?—I am not aware of any. Mr. Jesse, so far as I know, is treasurer and secretary.

6269. And so far as anything that appears to the contrary goes, he may have appointed the chairman and the committee?—Quite so.

6270. Can you tell me if any auditors are appointed, as is customary in a society that has to deal with funds?—I am not aware that that has been done. That is one of the things that I and other members of the committee are in communication about.

6271. Have you and the committee or other members of the committee, so far as you know, given

Mr. Jesse authority to speak in the name of the society on all occasions ?—No.

6272. To express opinions on behalf of the society? —No; I do not know of that authority having been given.

6273. You have never signed or passed any resolution to that effect; in fact there has not been any meeting I understand ?—I have not attended any.

6274. But you are a member of the committee ?—Yes.

6275. And would have been summoned to any meeting, I presume ?—Yes.

6276. We have had various letters sent by Mr. Jesse to this Commission, and in all those letters he speaks of himself as "the society's representative" (I quote those words), and he writes as if every letter were written by the authority of the society. May I ask if you have ever seen any of these letters? (if the Chairman will allow me I will hand them over to you to see), or if they have been written by your authority or that of any member of the committee ?—I do not suppose I have seen them. (*The letters were handed to the witness.*) No, I know nothing of these.

6277. Then they have not been written by your authority or so far as you know by that of any member of the committee ?—They have not so far as I know.

6278. And certainly the facts have not been submitted to any meeting of the committee ?—That is quite clear, there has been no meeting of the committee of which I know anything.

6279. We have also had laid before us various published letters from Mr. Jesse, letters forming part of correspondence with other persons, some of which are certainly worded in an exceedingly strong manner. In those letters Mr. Jesse speaks of himself as the representative of the society. Were those letters ever submitted to your committee ?—I am not aware that they were.

6280. So far as you can tell us, all this action of Mr. Jesse's has been entirely his own affair ?—Quite so. My belief is that Mr. Jesse got up the society probably with the concurrence of friends in his immediate neighbourhood; I do not know anything about that, but no doubt it is his creation to a great extent.

6281. And I suppose I may take it that practically he has appointed the president and the committee, and that practically everything that is done is his doing ?—I know nothing to the contrary. We have had informal meetings of two members of the committee who happened to be in town during the summer, but those are the only occasions on which there has been any sort of personal consultation between myself and Mr. Jesse.

6282. Had those meetings been called by Mr. Jesse ?—They were informal; I do not know how to answer that question; they were called with his concurrence.

6283. Was he present at them ?—He was at most of them.

6284. But those, not being regularly summoned meetings of the whole committee, of course could not be officially authoritative ?—No.

6285. Then further a number of printed documents have been issued in the name of the society, have you seen those ?—I think I have seen most of them.

6286. Did Mr. Jesse obtain any formal sanction from yourself or any other member of the committee, so far as you know, to the issuing of those documents ?—Not from me.

6287. You will observe that the point is of importance, because Mr. Jesse came before us professing to represent the opinions of a large body of highly respectable gentlemen. It is a matter of great moment therefore to us to ascertain whether he was really doing so, or was merely talking of his own motion ?—Well, as I stated to my Lord in the chair, I have been very much dissatisfied with the manner in which the society has been organized; my object in joining it has been to assist in the promotion of a definite object in connection with other persons whose views in the main I approve; I have been unable to organise it in the particular manner in which I wished to see it organised; and had I been well during the vacation the probability is that I should have either succeeded or retired.

6288. As respects the opinion which you quoted from a book, which you were kind enough to read to us respecting Harvey and his recourse to vivisection, I presume that you have not taken the trouble to go to Harvey's works yourself ?—No, I have not.

6289. And you are therefore not acquainted with a passage which has been before us from Harvey ?—I am not acquainted with Harvey's works; that is just one of the misfortunes arising from my having been laid up during the vacation.

6290. Will you allow me to read this passage to you: "When I first gave my mind to vivisections as a "means of discovering the motions and uses of the "heart, and sought to discover these from actual in-"spection, and not from the writings of others, I found "the task so truly arduous, so full of difficulty, that I "was almost tempted to think with Fracastorius that "the motion of the heart was only to be compre-"hended by God." And then a little further on,—"At length, and by using greater and daily diligence, "having frequent recourse to vivisections, employing "a variety of animals for the purpose, and collecting "numerous observations, I thought that I had at-"tained to the truth." Those are Harvey's own words, and I presume they will modify the opinion that you just now expressed with reference to him ?—My opinion is based upon the statement of Mr. Boyle's which I read.

6291. But these being Harvey's own words will probably carry more weight with you ?—I presume Harvey knew his own mind better than anyone else.

6292. Then as respects Bell, it is not worth while to trouble you upon that subject, but I presume in the same way you have not attended to the evidence on that subject ?—No, I have not had the opportunity of working the thing up as I wished to have done.

6293. I think I understood you to object to vivisection for the purposes of demonstration in medical schools, on the ground that it would accustom medical men to experimentation, and therefore would rather lead them in your judgment to experiment upon their patients, as interesting chiefly to scientific inquiry, rather than attempt to cure them ?—Yes, I should not wish to put it that it would lead them as a general rule to do that, but rather that one could never be sure that they were not doing it. That is what I meant to convey, that it would create distrust, because people could not be sure that the mind of the medical man was not rather directed to some interesting feature in the case which would lead to a scientific discovery than to the immediate welfare of the patient.

6294. Then I apprehend that that objection applies not so much to vivisection itself, as to the experimental method of which that is an exemplification; that a medical man having been used to the experimental method, would attempt to apply it to his patients ?—Quite so.

6295. Therefore in that case your objection would apply equally to all other modes of scientific inquiry which exemplify the experimental method; for example, there would be a parallel objection to the experimental study of chemistry, because that is purely experimental and brings to men's minds more than anything the necessity of experiments, hence there would be an objection in your mind perhaps to the experimental teaching of chemistry ?—No, I do not see that. I think that is one of the evils attendant upon experimentation of every kind that has to be guarded against. I do not say that that of itself alone would be sufficient to cause me to oppose vivisection. I give that as one of a number of reasons.

6296. Still, if a man is taught in any method whatever that experimentation in physical matters is the only way of ascertaining truth, surely the evil consequences of that belief, if there be any, must come out of any such teaching; it does not matter what the

Mr. J. M. Holt, M.P.

15 Dec. 1875.

subject-matter of the experimental teaching is, so long as a man gets it into his head that experiment is the thing to learn by ?—No doubt it trains him in a particular manner, which may predispose him to adopt objectionable practices.

6297. So that on the whole I take it that you think that even the experimental teaching of chemistry is not without its dangers; that it rather leads to make a man a worse practitioner than a better, or a more suspectable practitioner, I will say ?—You may put it in that form as to his being "suspectable;" but I do not say that that is sufficient to justify a distrust of a medical man.

6298. But I thought your objection was to his applying the experimental method to his patients. Now a man may become just as familiar with the experimental method by the study of chemistry or physics as by the study of experimental physiology ?—But there is no hardening effect in the chemical experiments; and it is the two things taken together which constitute the objection. My objection applies to experiments on living animals, not to other forms of experiment; though I feel that a medical man whose education has led him to form habits of experiment ought in practice to keep those habits under strict control.

6299. Now about the hardening effect upon men; is it within your experience that medical men show any less tenderness for the dead bodies of their fellows than other persons do; was there ever a case known of a medical man going with carelessness or disrespect towards a corpse ?—I am scarcely competent to answer that question.

6300. But if during these 300 or 400 years medical men, having been incessantly studying the anatomy of the human body, have not been led to be hardened on that subject, there is some ground for suspecting whether they would be hardened by witnessing experimental physiological operations, is there not ?—I have no personal knowledge of it, but one generally understands that medical students do not always exhibit the very greatest respect towards dead bodies.

6301. Then I understand you to express the opinion that it was generally admitted by medical men that vivisection is not necessary for teaching purposes. Have you made many inquiries among physiologists and medical men on that point ?—No, it is in my general reading upon the subject that I have gathered that there was a considerable amount of consent that there might be restrictions placed upon that portion of the practice.

6302. I put the question because the tendency of the evidence given to us has been the exact contrary. Now you further spoke of a "monopoly" at present enjoyed by medical men; would you be so kind as to explain what that means ?—I mean in the granting of certificates, and that sort of thing.

6303. In the granting of certificates of death for example ?—Yes, and vaccination, and certificates that are required if a man claims exemption in a court of law from serving on a jury or anything of that kind.

6304. You are a member of the House of Commons I think ?—I am.

6305. As such of course you take part in legislation ?—Yes.

6306. And I presume that your experience has convinced you that one of the essential conditions of a good law is that it should be respected by the persons whom it affects ?—Quite so.

6307. That if it is to be respected by the persons whom it affects, its operation should be equal, not partial ?—Yes.

6308. Now supposing that there were any abuse extensively practised, do you think that the legislation which fastened upon one particular fraction of that abuse and stopped it or interfered with it, and let all the other portion remain, would be likely to secure the respect of the community ?—I think it must depend very much upon the circumstances of each case.

6309. Supposing there were a liquor law passed to forbid certain persons from drinking champagne and to allow everybody else to drink as much as he liked, that is not a law which would commend itself to you ?—Not at all.

6310. Now that has a certain application to what we are considering at present. It will be within your knowledge, and the fact has already been brought out in Mr. Forster's questions, that an enormous amount of pain is inflicted upon animals for very various purposes. So far as those purposes relate to sport I understand your personal opinion to be that you do not think the infliction of this amount of pain justifiable ?—Quite so.

6311. I should like to ask you a question or two with respect to many well-known domestic operations. You are familiar with the castration of sheep and the spaying of sows, which is undertaken, not for the benefit of the animal, but simply to make it better for culinary purposes. Now, do you think that object one which justifies the amount of pain inflicted ?—I think it depends in each case upon the particular necessity which exists for it.

6312. That is why I ventured to put a particular concrete case to you. Take that of the castration of the lamb, or take that of the spaying of sows. The object there, there is no question about it, is simply to make them more easily fattened and rather better for the table. With that object many many thousands of animals are mutilated every year; and I wish to know whether you think that the object there justifies the operation and infliction of that amount of pain ?—My experience has not brought me into such contact with either of those operations as to be able to say what necessity there exists in the case. I presume that there are reasons for the castration of lambs, for instance, which may be sufficient. I am not prepared to express an opinion to justify it.

6313. In the case of the spaying of sows, there is no doubt whatever about it, that it simply enables the farmer to fatten the sow a little faster; nobody ever doubts that that is the reason. Would you think that sufficient to justify the amount of pain inflicted, for it is a very severe operation ?—No, I should not.

6314. Take another case; many many thousands of rabbits are brought into Billingsgate market every day; the great majority of those rabbits have been caught in traps, the operation of the trap is such that the rabbit is caught and very often held in intense torture for five or six hours till the keeper comes and takes it out and knocks it on the head. The human race could very well do without rabbits. Do you think that the object attained in that way is sufficient to justify the amount of torture inflicted ?—I think it is a very cruel method of catching them.

6315. I think I might, only it would occupy the time of the Commission too much, put before you a number of similar cases. Now, while this enormous amount of unnecessary pain, or what may be assumed to be unnecessary and severe pain, for very inadequate objects indeed, is being inflicted, is it your opinion that it is a practically fair and equitable legislation to meddle with the comparatively small amount of pain inflicted for scientific purposes, and leave all the rest untouched ?—I should be glad to see a larger measure than one merely addressed to scientific purposes.

6316. You would like to make this measure equal in its operation with regard to all similar classes of what you consider offences ?—It would require very careful consideration how it should be dealt with, but I should like to see not a measure to deal with vivisection alone, but a measure to deal with the cutting and wounding of animals generally.

6317. In fact, you are prepared to apply your principle logically and consistently to all cases which could be shown to come under it ?—I hope so.

6318. Now let me put one other inquiry to you. There seemed to be some doubt in your mind whether vivisection had ever furnished a practical medical man with knowledge valuable to mankind. I do not know exactly whether you may have heard of Dr. Brown-Séquard ?—I know the name.

6319. Who was an exceedingly eminent vivisector, Mr. J. M. Holt, M.P.

15 Dec. 1875.

and who during one period of his life spent some four or five years in London, and became a practising physician. He treated specially the diseases of the nervous system, and his knowledge acquired by vivisection was of such a character, in its application to the relief of disease, that he very rapidly had an enormous practice, and no doubt did more than any other man of his day for the relief of human suffering. May I ask whether, supposing you yourself had had the misfortune to suffer from epilepsy or paralysis, you would have absolutely refused to take advantage of Dr. Brown-Séquard's knowledge; or rather, I will not ask you whether you would have refused to do so (because we do not always ourselves act up to our own principles), but whether you would have thought it wrong to do so?—I should have done it very reluctantly.

6320. May I ask if you had had a relative suffering under such a form of disease, and had good ground for believing that Dr. Brown-Séquard would have cured that relative, would you have thought it a wrong thing to take Dr. Brown-Séquard to that relative?—I do not think I should have done it.

6321. (*Mr. Hutton.*) I take it that you would not object to allow the police to make use of the knowledge that they had acquired from burglars in order to prevent burglary, would you?—Well no, I do not know that I should.

6322. Therefore it does not follow at all that because you object to vivisection you should object to use the knowledge acquired from vivisection in the cure of disease?—I cannot see it myself.

6323. I take it that what you meant with regard to the danger you apprehended to the profession from the practice of vivisection was not lest the method of experimentation should lead to abuses, but lest the method of experimentation on suffering should lead to abuses?—Quite so, experimentation upon suffering.

6324. Your idea was, for instance, that if a medical man would not object, according to evidence which we have had before us, to put a dog to very considerable pain for eight or nine hours for the sake of finding the effect of rhubarb upon its liver, he might conceivably not object to put a being differing not very greatly from a dog to a certain amount of not much less pain for the sake of finding the effect of rhubarb on his liver?—Yes.

The witness withdrew.

Mr. G. H. Lewes.

Mr. George Henry Lewes called in and examined.

6325. (*Chairman.*) You have devoted yourself a good deal to the study of physiology and the practice of physiological experiments?—Yes, especially during the last 20 years.

6326. You received originally, I think, a medical education?—Yes.

6327. And therefore acquired sufficient familiarity with the subject for that purpose?—Yes.

6328. Have you been a great deal in foreign laboratories?—Principally. I know little of the English laboratories.

6329. But you have formed opinions upon the subject which has been referred to our consideration?—Yes.

6330. Will you have the goodness to state them to us?—Briefly, my view is that vivisection as a portion of experimental science is indispensible, is a necessity, but that it is a very painful necessity; and that being a very painful necessity, each experimenter should consider the question of pain in determining whether he will perform an experiment or not. A great deal of experiment is quite useless; useless because it very often could not prove what is attempted to be proved. The organism is so complex that when you produce even a slight disturbance you are seldom certain of what other disturbances you produce; so that an experiment which seems quite decisive by the phenomena it presents, will turn out to be totally indecisive, because the same results may be obtained by a totally different experiment. I will cite a brief instance. Owsjannikow published an account of the effect of destroying certain ganglia of a crayfish; he did nothing else but destroy these ganglia; and it seemed as if the phenomena were the consequence of that. Meyer immediately afterwards cut off the large nippers of the crayfish, and the same phenomena were observed; he had not touched the ganglia, and yet he got the same result. In the case of the innervation of the heart I scarcely know a single statement which has been made that has not been contradicted by somebody else; and so on. In consequence of this extreme complexity of the organism, and the difficulty of determining the effect of any disturbance, the experimenter requires a very powerful imagination to picture to himself what will probably be the result of the experiment that he is going to perform. When it is a painful experiment, when there is a great mutilation necessary, I think the experimenter is bound by moral considerations to weigh very well and carefully with himself what are the probabilities that this experiment which he is going to perform will have the result that he anticipates, or will have any result at all that is distinguishable from some other disturbance. But I think it is so utterly impossible to lay down laws or general rules in this matter that even physiologists could not always determine when an experiment should be performed, unless they had the whole of the case before them. Each man really must determine it for himself. But a considerable amount of experiment might be got rid of if the students were early impressed, firstly, with the belief of the excessive difficulty of getting at any result: a belief which would prevent any experiment being lightly undertaken; and secondly, to consider whether any experiment that involved great mutilation should be performed at all, unless under a profound sense that it was necessary, and likely to yield a valuable result. At present our journals are crowded with reports of experiments. One man discovers a fact or publishes an experiment, and instantly, all over Europe, certain people set to work to repeat it; they will repeat it, and repeat it, and repeat it. Now it is quite unnecessary to repeat an experiment as to a fact that has been well observed. Of course it will require confirmation, but it does not require to be repeated often; as soon as it has been once established, I think you should have some reasonable doubts of the validity of the fact before you repeat it.

6331. In point of fact it requires a person of very great powers of mind really to form a just conception of whether an experiment will be of service or not?—Decidedly; and even then he can do it only with a very obscure sense of the probable results.

6332. I need not ask you whether a great multitude of persons must necessarily be entirely incompetent for any such office?—Entirely.

6333. And whether, therefore, it is not important that, if possible, the discharge of such a function should be limited to the class of people you have spoken of as the only class competent to perform it properly?—Certainly.

6334. And if, therefore, society should endeavour to take some steps for limiting the discharge of those functions to such persons, society would be acting in its right and in its duty, would it not?—Yes; but there is this difficulty, that a man who may not be a recognised physiologist may yet, in fact, be a physiologist. For instance, I should not have been recognised; I am a member of no medical college; I am not a member of the profession; and yet there are very few members of the profession who have done more physiological work than I have. I should be excluded, upon the supposition that only physiologists who were recognised as such were allowed to perform these

Mr. G. H. Lewes.

15 Dec. 1875.

experiments. When I began my work I should have been excluded and not allowed to perform experiments. That is one difficulty. I say, therefore, that it seems to me it is a question to be determined by each person and in each case. It seems to me that the vivisection of which we are now speaking is very much like vivisection in another department, that of Literature, that is to say, criticism, which is also vivisection. There is a great deal of real torture inflicted upon authors by critics, which lasts for a considerable time in sensitive minds.

6335. (*Sir J. B. Karslake.*) And without anæsthetics ?—And without anæsthetics.

6336. (*Mr. Erichsen.*) And by incompetent persons ?—Not only by incompetent persons, but by persons who, even when they are competent, are often reckless. It is quite true that for the benefit of literature, and consequently of society, criticism is a necessity ; and I suppose that everybody possessed of right feeling, who has exercised that office, has often felt great pain in giving pain. But a great many people do not feel any pain at all about it ; a slashing review is a thing that they like.

6337. (*Chairman.*) Is there not this difference, that you may get so much accustomed to the moral vivisection, of which you speak, as to become indifferent to it ?—Public men may get indifferent to criticisms which they get every day ; but I do not think that actors and authors, who do not get it every day, get accustomed to it.

6338. But I suppose you would scarcely compare that in point of necessity of control with the fact of living animals being cut up ?—Why not ? Surely here are human beings who suffer frightfully ? I do not think you could control that ; but then I do not think you could control vivisection profitably.

6339. Do you not think it would be possible to contrive some arrangement by which utterly ignorant and incompetent people should be prevented from exercising their fancy in cutting up living animals ?—If I thought that ignorant people did it, I should certainly say that they ought to be stopped, if possible ; but as far as my observation goes, even medical students are extremely reluctant to perform experiments at all. They do not like to follow anything which gives them much trouble ; and the outside world certainly do not, except from mere cruelty and love of tormenting. Experiment is very troublesome and tiresome ; and the students have not generally sufficient intellectual interest in the result to take the trouble involved.

6340. (*Mr. Erichsen.*) And their time is much occupied in other matters ?—Yes. When I was in Munich a great many years ago I assisted in preparing the heart of a frog for Professor Bischoff's lecture ; there were six preparations made, and the students had only to look through the microscopes and they would have seen the ganglia of the heart which perhaps they never would have seen otherwise ; and yet, although these six microscopes were there for these students to look through, if they chose to take the trouble, when the lecture was over there was not a single one that did.

6341. (*Chairman.*) Is there any pain inflicted upon these frogs so put under the microscope ?—No ; it was only the dead heart. So little interest do students habitually show in anything like scientific inquiry which is not to come into their examination, that I do not fear at all that there will be much experimenting done by students who are ignorant. But as to the students who are curious and of a really scientific bent, that is another matter ; they may be, and I think ought to be encouraged to perform experiments.

6342. Would you encourage an unpractised student to perform painful experiments ?—No, certainly not ; no experiments at all. He should be made to feel the excessive difficulty of reaching any valid result, until a large knowledge guided him.

6343. If I collect your opinion rightly, you see difficulty in providing any control or restriction, but if control or restriction could be provided, which should operate upon the unpractised and the incompetent, it would not go contrary to your views ?—I should look with great jealousy upon anything like a definite restriction. In each individual case the professor should discourage, I think, the needless performance of experiments.

6344. But I understand you to say that you may read every day in published medical journals of experiments all over Europe which are unnecessary repetitions, which are abuses of the power of man over the lower animals, and which therefore I presume you would be glad to see restrained if you could ?—Decidedly.

6345. And therefore it is only the difficulty of accomplishing the object which is in your mind the objection ?—Yes. My difficulty is that anything like a definite restriction would very seriously interfere with the prosecution of the science. If it did not, then I could only wish it to be done. I think for the sake of science it ought to be restricted ; but I think it must come from the professors themselves inculcating a sense partly of responsibility to the animals, and partly of responsibility to science, not to encumber science with useless lumber, which the mass of it is. And I think that the repetition of experiments for confirmation of established facts is very unjustifiable. It is difficult of course to say what is established and what is not ; but unless you have a doubt, and a rational doubt upon any one point, you ought not to put an animal to any inconvenience even—I will not say *pain*, because there is really very little pain going on (that is to be observed), for the pain of an operation is in the *wounding*, not in the *wound*. The wounding is almost always done under chloroform or ether, for various excellent reasons ; unless you want to test the pain, then of course you do not use anæsthetics. When the animal recovers he has got a wound ; he may sometimes be dreadfully mutilated ; but habitually he has simply a wound which is of very little consequence. It is not as with us ; unless inflammation sets in afterwards, the wound is of very little consequence. I have seen a rabbit wake out of the narcotic state with its spinal cord cut in two, and begin to eat a cabbage as if nothing whatever had happened ; so that there really is very little pain. I should not care to put that forward however, and make people say that vivisection is not painful, because there is a good deal of it which is as bad as pain. You disable an animal, and it is a cruel thing to an animal to disable it ; but there is very little pain, as absolute pain, when chloroform is used.

6346. (*Lord Winmarleigh.*) At the same time I suppose you would not deny that if an animal has been experimented upon and is allowed to live afterwards, the wound that has been inflicted may be the cause of great pain to it ?—It would depend of course upon the nature of the wound ; but the wound heals very rapidly. I saw a bitch in Goltz's laboratory that had its spinal cord cut through when a puppy ; and it was a lively bitch, and bore pups afterwards ; and yet that cutting of the spinal cord is a terrific operation.

6347. Did I apprehend you rightly to state that you thought that no experiment should be made without a definite object ?—Certainly. I think morally every man is bound not only to have a definite object in performing an experiment, but also only to perform it after due consideration of whether the experiment could have the result, or any available result.

6348. You would object altogether to a man making an experiment to see what would come of it ?—Altogether ; it is preposterous. Not only that, but I should object to his doing it without due consideration of the anatomical relations, or without the necessary physiological knowledge.

6349. I daresay you are aware that the object of this Commission is to recommend a course to be adopted on this subject. Could you yourself suggest what you think would be the best mode of preventing any unnecessary cruelty in this respect ?—No. As I have said, no more than I could suggest how you are to

Mr. G. H. Lewes.

15 Dec. 1875.

prevent the unnecessary cruelty in criticisms; yet there is a great deal of it.

6350. You must leave it to the good feeling of people, you think ?—Yes; unfortunately a slashing review is very popular, and therefore the critic is encouraged in doing what he would not if the public disapproved of it. Now if the scientific public strongly disapproved of useless experimentation, that would be a check.

6351. You say that you have been abroad a good deal ?—Yes.

6352. Is there a country that you know of in which there is any legislation upon this subject ?—No.

6353. (*Mr. Forster.*) You have studied physiology very much, although you state that you would not be considered a professed physiologist ?—Abroad I am recognized, but I should not be recognized in England as a physiologist by any constituted body, because I have no diploma.

6354. In your study, and for the objects of discovery which you have had, you have yourself tried a good many experiments ?—A great many.

6355. Do you know of any other investigators like yourself who are not connected with any of the physiological schools, who are not professed physiologists, who try experiments ?—No; I know very few, even among physiologists, who do.

6356. When you speak of this constant repetition of an experiment, I suppose you do not mean by that that there are a great many people like yourself who would be trying experiments, but without the same care to avoid useless repetition ?—No, I think there are few people who perform experiments at all in England; I wish there were many more.

6357. I was going to ask you a question with regard to the mode in which you have conducted your experiments, and I will explain the reason why I do it. You are the first what I may call private investigator that we have seen. We have asked the public investigators who have come here questions as regards the manner in which they have conducted their experiments, and therefore if I ask you the same question you must understand that it is not from any suspicion of carelessness on your part, but merely that we may obtain information on that part of the subject. Now about how many animals in the course of the year would you be likely to experiment on ?—That I could not answer, because my experiments have been mostly upon frogs and other cold-blooded animals. They have been almost exclusively upon those; and they have been done in great quantities when they have been done at all. Sometimes it would be several frogs to a single experiment, sometimes a single frog would suffice.

6358. Would that be a painful experiment or not ?—It might or might not. If you mean an experiment in which the animal would feel pain, that would be very rare indeed; it is only when you want to determine the effect of pain, *as* pain, in checking the action of the heart, for instance, that you do not etherize; but I should say that in 70 cases out of 80 the frogs are etherized.

6359. That is the anæsthetic which you employ for the frog ?—Yes, because chloroform almost always kills it.

6360. Have you tried any experiments upon dogs or cats ?—No, I could not bear it.

6361. Rabbits ?—Yes.

6362. Can you give us the number of your experiments on rabbits, or any warm-blooded animal ?—Very few rabbits, and pigeons.

6363. A dozen of rabbits or pigeons in the course of the year ?—No, not more than that in as many years.

6364. When you do try experiments on warm blooded animals, you give anæsthetics ?—Yes.

6365. I suppose in every case except where the experiment relates to the nerves ?—Almost all my experiments were relating to the nervous system.

6366. When you give anæsthetics what do you give ?—Ether for the frog, and chloroform or ether for the warm-blooded animals, and sometimes chloral.

6367. When the animal recovers from the chloroform or other anæsthetic do you, in case of its being likely to suffer much pain, kill the animal at once, as long as it can be done without sacrificing the experiment ?—Always.

6368. Have you ever used wourali or curari ?—No.

6369. Have you formed any opinion as to whether it really is an anæsthetic or not ?—It is probably an absolute anæsthetic.

6370. What we have had brought before us is that there was originally very great doubt whether it was an anæsthetic in the sense of depriving the animal of sensation, though it did deprive it of mucular motion, and that now there is some little difference of opinion on the question ?—I should add that I disbelieve entirely in sensation—I mean *conscious* sensation—without motion.

6371. Then it is your opinion that inasmuch as curari destroys the animal's power of motion it also destroys sensation ?—It would take too long to explain my meaning, but I will merely say that no sensation so complex as that of pain could be produced in an animal that had been curarized.

6372. I do not want to ask you the name of any operator abroad, but would you consider that there is a different feeling with regard to the prevention of pain in these experiments on the continent from what there is in England ?—Very great; and a difference between France and Germany. The French and the Italians are very much more indifferent to the question of pain than the Germans are; strikingly so. And it is the same in Italy, partly I believe owing to the indifference of the whole nation to the sufferings of animals. In Italy and Spain the people are more cruel to their animals than they are in either France or Germany.

6373. Without comparing France and Germany, you would say that in England the feeling is decidedly more in favour of the animals ?—Decidedly stronger.

6374. But I think you said that you wished there were more experiments, and I suppose you would think that the progress of experimental science altogether would have a tendency to cause more experiments to be made ?—Yes, what I wish is that there should be more thoughtful experimenters, and fewer needless experiments.

6375. But do you not think that without some kind of legal provision there would be some danger of England following the example of France and Italy ?—Not the least.

6376. Why do you think so ?—Because it is entirely a social difference. I should say the state of feeling in Italy and Spain with regard to animals (I begin with those), from the lowest strata of society upwards, is different from what it is in England. I do not wish to assume for ourselves a moral superiority, but our morality has certainly been cultivated in the direction of greater sympathy with animals; and of course the surgeons and medical men are taken out of the general mass of the population, and in those countries of which I have spoken they bring with them what I should call the national indifference. In England we are not indifferent to those things; at least not so much; there is a great deal of indifference in England, but still it is less. Then I may say, without naming them, that two of the very greatest experimenters in Europe whom I have seen at work (not in England,) always use anæsthetics; and one of them many years ago explained to me why it was that he did so: not in the least out of consideration for the animal, but entirely out of consideration for the perfection of the experiment: that he might know what he was doing. If you have an anæsthetized animal it lies like a log of wood before you; it does not move, it does not flinch, and you can make the most delicate operation with certainty; you know how far you cut.

6377. For that purpose curari would answer for him ?—Perfectly.

Mr.
G. H. Lewes.

15 Dec. 1875.

6378. And do you think he generally used curari?—No, chloroform.

6379. (*Mr. Hutton.*) You said that you had performed many hundreds of experiments, and some of them extremely painful, but in very rare cases. Would you give us instances of the very rare cases in which they have been extremely distressing to yourself?—Well, it is always distressing to hear the cries of an animal or witness its struggles; to me especially, being very fond of animals, and so much so that I could not see experiments upon dogs.

6380. But would you give us an instance or two of the most distressing experiments that you have performed. Have you ever performed Goltz's experiment of boiling a frog till it died?—No; but to disprove his conclusion, I dipped a frog in boiling water.

6381. A frog without its brain having been destroyed?—No, the brain had been removed.

6382. Do you suppose that the frogs suffer very much under that?—No, I do not. Personally, I do not believe that even when they have the brain frogs suffer pain at all; but I should not like to state that publicly, because it would seem like an attempt to justify our practice on equivocal grounds. I should justify it even if the pain were there.

6383. What grounds could you give us for that supposition that frogs do not suffer?—Because we know that the great mass of our own sensations are totally divested of pain and cannot be exaggerated into pain; even with hyper-æsthesia there is often no pain. We know that among human beings, especially when you descend to the savages, the sensibility to pain becomes less and less. Coming to animals, we know that, for instance, a horse that has had his leg shattered in battle will crop the grass, which no animal in great pain could do. There has been an immense mass of evidence collected, which I cannot at this moment recall, showing that pain is quite a special form of nervous sensibility. We know that anæsthetics destroy pain without destroying sensibility; a patient will feel the surgeon's knife, but no pain; and in certain diseases an increased sensibility to touch and temperature co-exists with absolute insensibility to pain. On any evidence that I have before me I should say that the fishes and the reptiles have sensibility, but none of that which we call pain.

6384. But your answer applies to horses quite as much as to the lower animals?—I say they do not suffer the pain that we do; yet a horse's skin is excessively sensitive, as we know.

6385. Then you do not agree with the opinion that has been expressed before us, that there is more real difference between one individual and another individual in the same species in point of pain than there is between individuals of different species?—No.

6386. Can you give me any account of an experiment on one of the warm-blooded animals that you thought extremely painful?—Well, dividing the spinal cord and cutting the roots of a spinal nerve.

6387. Is that the one on recurrent sensibility?—No; simply the dividing the roots of the nerve.

6388. Then, I suppose, you performed that under chloroform, did you not?—Yes.

6389. But the irritation afterwards was without an anæsthetic?—Yes; it was not feasible to give an anæsthetic afterwards.

6390. Was that on a rabbit?—On a rabbit.

6391. Did that experiment answer its object? Did you discover something?—No.

6392. It was an ineffectual one?—Quite.

6393. Do you not hold some rather peculiar views about the phenomena of reflex action?—Yes.

6394. You differ from the physiologists in general, do not you, as to the action of the spinal cord?—Yes; I believe that sensibility is present in all reflex action.

6395. You mean by sensibility, not suffering, I understand?—No; sensibility.

6396. (*Lord Winmarleigh.*) What is the difference?—For instance, you have in the eye sensibility to light, but you have no pain in that at all. Your optic nerve might be cut through and you would have a vivid sensation of light, but none of pain.

6397. (*Mr. Hutton.*) You mean a kind of consciousness, do you not?—It may be a kind of consciousness: that is a question of definition.

6398. (*Lord Winmarleigh.*) Then it is the extent of the sensibility that is pain, is it not?—No; you may have exaggerated sensibility without any pain.

6399. Take the instance of a worm. You put a hook into a worm and there are violent contortions; that we are told is reflex action?—There may be or may not be pain, but the contortions do not prove pain at all; no more than the struggles of a patient under chloroform.

6400. But there would be sensibility there?—Yes.

6401. (*Mr. Hutton.*) May I put this question to you to raise the point. Do you hold, for instance, that supposing a complete frog would suffer by being put into boiling water, then a frog with its brain destroyed would suffer equally by being put into boiling water, or would suffer in a proportionate degree?—No; it would not follow. When you have removed the brain you have removed a great part of the nervous organism.

6402. Still, would you hold that some suffering would remain in the brainless frog?—No; no *suffering* at all, but sensation.

6403. Then the same kind of power of sensibility is not in the spinal cord as in the brain itself. It is not a mere question of degree, I mean?—No. You would say that the sensibility of the eye or the optic apparatus to light was different from the sensibility of the auditory, and that again different from that of the gustatory, but all three are forms of sensibility, and the form known as pain is quite as special.

6404. Do you suppose that the lower part of a man whose spinal cord is divided suffers, although he is not conscious of the suffering, when any painful operation is performed on his lower limbs?—How do you use the word "suffering," may I ask?

6405. That there is an animal, though not that animal which is conscious, through the brain, that is suffering; that there is a part of the animal that is suffering?—Certainly; I believe that there is sensibility, or as we say that the leg feels it. I believe that a fragment of the spinal cord has the same sensibility that the whole spinal cord has, and the whole spinal cord has the same as the whole spinal axis, including the brain; but the forms this sensibility assumes depend on the organs innervated.

6406. Supposing a case were brought before you as it has been brought before us, of a man under the action of curari, who, although he could not stir a muscle and had to have respiration kept up by artificial processes, gave a full account of all that happened to him during the action of curari; would you not argue from that, that it was quite possible that sensibility would remain after the motor power was absolutely destroyed?—But what motor power? Were all the muscles destroyed, or simply the ability to move his limbs?

6407. All the motor power?—You must remember that there may be motor vibrations going on without a limb being moved.

6408. As I understand even the power of breathing is entirely destroyed in that case without artificial respiration?—I do not know such a case.

6409. And you do not believe in it?—I cannot say that I do not believe in it. I do not know it.

6410. I understood you to say that you did not believe that motor action could be destroyed without sensibility being destroyed?—I should have limited that; I should not have said motor action, but rather motor impulse; because if the muscles do not contract synchronously there will be no movement of the limbs, and yet every muscle and fibre may be in a state of vibration itself; but they do not contract synchronously.

6411. (*Chairman*). Before you go let me ask you one question,—do you consider that in the training of

Mr. G. H. Lewes.

15 Dec. 1875.

medical students in physiology it is necessary that they should see experiments performed before their eyes?—Well that again would depend upon the nature of the experiment. Many experiments may be rendered so intelligible that a diagram would do; in such cases experiment is *very* objectionable; but in more complex cases they must be seen. It impresses the facts upon the student to see the experiment.

6412. You consider that to state that medical students could be completely trained without having seen experiments on living animals would be a mistake?—Yes, they must see some.

6413. (*Mr. Erichsen.*) You stated, I think, that in performing experiments on warm-blooded animals your feelings prevented you from using dogs and cats, and you invariably had recourse to a rabbit?—Yes, or a pigeon.

6414. Do you think that a rabbit may be substituted for a dog or cat, as a general rule, in all experiments on warm-blooded animals?—I should not like to say that.

6415. Do you think that there are cases in which it could not be used with advantage?—It would entirely depend upon what the man was going to prove. I could not myself use dogs or cats.

6416. I simply meant to ask whether in your opinion a rabbit, as a general rule, could be substituted for other warm-blooded animals, say a dog or a cat?—As a general rule it is, because it is much more tenacious of life and much cheaper.

6417. But there are cases you think in which it could not be substituted?—I should not like to express any definite opinion on that subject.

The witness withdrew.

Adjourned.

Monday, 20th December 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
THOMAS HENRY HUXLEY, Esq.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

Mr. GEORGE RICHARD JESSE recalled and further examined.

Mr. G. R. Jesse.

20 Dec. 1875.

6418. (*Chairman.*) When your last examination closed, we understood that you wished to say something more?—Yes.

6419. Will you be so good as to tell us what it is?—The Society for the Abolition of Vivisection wishes to observe, that evidence, such as it has been giving to Her Majesty's Commissioners, of the torture of animals for so-termed scientific objects, the corrupting moral influence generated by these practices, and the errors and fallacies spread abroad by them, it can continue to give, if Her Majesty's Royal Commission is not satisfied that, from the mouths of vivisectors, the Society has proved them to be all that it has asserted of them in the opening statement which it made before this Commission. The Society wishes respectfully to inquire of Her Majesty's Commissioners if they are convinced on these points, and if not, what further evidence they require?

6420. The Commission have given you the opportunity which we understood you to ask for, to give further evidence before us, and we are now assembled for the purpose of hearing you?—Very good. Then we wish to tender in further evidence the opinion of the late Sir Charles Bell, the eminent surgeon, who has said, "Anatomy is already looked on with pre-" judice; let not its professors unnecessarily incur the " censures of the humane. Experiments (vivisec-" tions) have never been the means of discovery; " and the survey of what has been attempted of late " years will prove that the opening of living animals " has done more to perpetuate error than to enforce " the just views taken from anatomy and the natural " motions." Again, Sir Charles observes, "In a " foreign review of my former papers the results have " been considered in favour of experiments (on living " animals). They are, on the contrary, deductions " from anatomy; and I have had recourse to experi-" ments, not to form my opinions, but to impress " them on others. It must be my apology, that my " utmost powers of persuasion were lost whilst I " urged my statements on the ground of observation " alone."

I will now quote from "The Life and Labours of " Sir Charles Bell, by Amédée Pichot, M.D. " London: Richard Bentley, New Burlington Street, " Publisher in Ordinary to Her Majesty, 1860." At page 68, speaking of one of his ideas, he says, "He " thought more of it for his own gratification than for " the benefit of others, and at last brought himself to " a conviction that the pursuit of his discovery was " the egotistical gratification of a scientific vanity. " In this point of view he looked upon it as an act of " barbarism to sacrifice living animals to his fruitless " experiments. 'I should be writing,' he said to his " brother, 'but I cannot proceed without making " 'some experiments, which are so unpleasant to " 'make, that I defer them. You will think me " 'silly, but I cannot perfectly convince myself that " 'I am authorised in nature or religion to do these " 'cruelties. For what? For a little egotism or " 'self-aggrandisement. And yet, what are my " 'experiments in comparison with those which are " 'daily done for nothing?' This sensibility made " Sir Astley Cooper smile, for to his human autopsies " he added hecatombs of animals. Fortunately, too, " it did not prevent Charles Bell from becoming a " brilliant operator. His 'System of Operative " 'Surgery' (a work published in 1807, which has " gone through three editions) contained no descrip-" tion of an operation he had not himself performed; " from 'bleeding in the arm, to lithotomy with the " 'knife alone; from tying the umbilical cord, to the " 'Cæsarian section.'" So that in his case, one of the most brilliant operators, vivisection was not necessary. At page 127 I find this, "In his study of " the system of circulation, as in that of the nerves, " Charles Bell was necessarily compelled to make " more than one experiment in comparative anatomy, " but he abstained as much as possible from torturing " animals, which he considered, in most cases, a " useless act of cruely, less certain in result than was " commonly supposed, and less profitable than an " attentive study of pathological phenomena, because " vivisection not only alters the substance of the " mutilated organs, but disturbs, more or less pro-" foundly, the natural condition of life, and excites " through pain irregular motions, differing from " those expected or previously observed, &c. He " admits that such is not the opinion of some of the " best and most virtuous men he has ever known, but

Mr.
G. R. Jesse.

20 Dec. 1875.

"that for his own part he never could convince himself "either by the experiments he witnessed or by any "of those related to him." At page 140 I find this, "The function of the cerebellum is demonstrated as "regards animals, but man has not been subjected to "these experiments like rabbits and pigeons. Pathology "alone could not tell us whether there is a "perfect identity here between the human and "animal creation." At page 118 it says, speaking of an experiment which he wished to perform, that "he never could be induced to make the first experiment "on a human subject," though he tried it on a monkey. Our object in reading those two passages is to show the tendencies on the part of these men not to stop with the animals in their experiments.

(*The witness was directed to withdraw.*)

(*After a short time, he was again called in.*)

6421. (*Chairman.*) The Commission wish me to suggest to you that the opinions of this writer upon Sir Charles Bell and his conduct —— ?—Excuse me for interrupting you, but I am not reading the opinions of Pichot, but those of Sir Charles Bell himself.

6422. Will you allow me to say first what the Commission wish me to say, which is that their opinion is that the views of this writer upon Sir Charles Bell are not evidence which is likely to assist them in forming their judgment ?—I thought I had confined myself to what he quoted from Sir Charles Bell's writings; but at all events in future I will take care, as far as I can, in reading from the book, to confine myself to Bell's statements.

6423. You will allow me to say that this is the third occasion on which we have had the pleasure of seeing you, and we are desirous now to bring your evidence within proper and practicable limits ?—Of course. I have no wish to the contrary. I am not here from pleasure. Then at page 202 I read this: "'Pain,' remarks Sir Charles Bell in his 'Anatomy "and Philosophy of Expression,' 'is affirmed to be an "'unmitigated evil; yet pain is necessary to our "'existence. At birth it rouses the dormant faculties, "'and gives us consciousness. To imagine the absence "'of pain is not only to imagine a new state of "'being, but a change in the earth and all upon it. "'As inhabitants of earth, and as a consequence of "'the great law of gravitation, the human body must "'have weight. It must have bones as columns of "'support and levers for the action of the muscles; "'and this mechanical structure implies a complication "'and delicacy of texture beyond our conception. "'For that fine texture a sensibility to pain is "'destined to be the protection; it is the safeguard "'of the body; it makes us alive to those injuries "'which would otherwise destroy us, and arms us to "'avoid them.'" We give that evidence from Sir Charles Bell, because it is stated that many of these experiments are made with a view to the alleviation of pain. Some people seem to think that pain may be in time entirely abolished.

At page 198 there is this quotation from Sir Charles Bell: "Whoever has sat on a sunny stone in the midst "of a stream, and played with the osier twigs and "running waters, must, if he have a soul, remember "the day should he live a hundred years; and to "return to such a spot after twenty years of a struggling "life in the great world of man's invention; to "come back thus to nature in her simple guise; again "to look up to the same dark hill; again to the same "trees, still in their youth and freshness; the same "clear running waters;—if he can do this, and think "himself better than a cork floating on the stream, he "has more conceit than I." The book proceeds: "The great Newton, a short time before his death, "uttered this memorable sentiment: 'I do not know "'what I may appear to the world, but to myself I "'seem to have been only like a boy playing on the "'seashore, and diverting myself in now and then "'finding a smoother pebble or a prettier shell than "'ordinary, whilst the great ocean of truth lay all "'undiscovered before me.'" Men are very apt to exaggerate the value of these discoveries, as they call them. We think it is well to show what a really great mind thought of his discoveries, which were of vast importance to mankind.

6424. You must allow me to suggest to you that we have many of us heard that passage from Sir Isaac Newton before ?—I have no doubt of it.

6425. And that what we want is evidence which has some reference to the question of trying experiments upon living animals, into which alone the Crown has commissioned us to inquire; and the evidence which you have given us in the two last passages appeared to me not to have the smallest bearing whatever upon the subject referred to us by the Crown ?—I am sorry, my Lord, you should think so. To us they seem very cogent and to the point, for the reason which I have just stated. I have given the opinion of a very eminent modern surgeon. I will now give the opinion of a Roman surgeon, as corroborating Sir Charles Bell. I have here a translation of the eight books of Celsus on Medicine, second edition, by G. F. Collier, M.D. London: Simpkin and Marshall, 1831. At page 7 I find this: "But now "remains . . . . the "most appalling."

6426. Do you quote that as showing anything bearing upon the subject to which our inquiry has reference ?—I am surprised, my Lord (I say it with all courtesy), that you should ask me such a question. I am reading, as I said, the opinion of a Roman medical man on the subject of vivisection.

6427. You think it calculated to assist us in coming to a conclusion ?—I should think so, most decidedly. Most emphatically do I say so. It ought to do so. That he was no ordinary man this is a proof: here is a translation of his book by an English physician, made only a few years ago. At page 13, I find this: "To return to . . . . "conformable to humanity." I propose now to quote from the "Sporting Magazine," January 1825.

6428. What do you propose to read us the "Sporting Magazine" for ?—To show the opinion of a very skilful man, a veterinary surgeon, in regard to vivisection.

6429. In the year 1825 ?—That is the date of this volume; perhaps not of the particular number of the "Sporting Magazine."

(*The witness was directed to withdraw.*)

(*After a short time he was again called in.*)

6430. (*Chairman.*) The Commission wish you to confine yourself to evidence directly calculated to assist them in coming to a conclusion upon the point referred to them, and they wish me to repeat to you their opinion that some of the passages which you have recently quoted are not of that character ?—Well, I am at a loss what to do, because the evidence that our society wishes to tender to the Royal Commission through me, the Commission thinks is not to the purpose.

6431. The Commission think that some of that which you have tendered is not at all calculated to assist them in coming to a conclusion. They wish you in your future evidence to furnish them with that which may render them some assistance ?—That is what I have been trying to do all along; it appears that I have not succeeded. I thought that the opinion of this man, this veterinary surgeon, a man of considerable eminence, had, at all events, a value as his opinion.

6432. What we understand you to tender to us is an opinion ?—I hope that you will not think the worse of it because it is in the "Sporting Magazine;" it is anything but trifling.

6433. What we understand you to tender to us is an opinion expressed in the "Sporting Magazine" in 1825, that is to say, more than 20 years before the discovery of anæsthetics, upon the subject of the Bill brought in by Mr. Martin ?—Yes.

Mr. G. R. Jesse.

20 Dec. 1875.

6434. We do not think that that is calculated to assist us in the inquiry which we are prosecuting?—I am sorry to hear it, because we thought we had convinced the Commission by this time that as to so-called experimenting on animals under anæsthetics, it was, in the great majority of cases, a mere delusion and a snare in regard to the public. Among those that I mentioned, I gave a very recent instance in which Professor Ferrier was concerned, and you saw what that amounted to,—the animals uttering shrieks and gnawing their own legs, and giving excessive manifestations of agony; and yet one gentleman says they felt no more than a pianoforte. We will leave the public to judge of that, with the common sense of the English nation.

6435. We should be obliged if you will have the kindness, in your future evidence, to give us what is directly to the point?—I must hold my ground as to that. I believe that is what I have been doing. We differ, unfortunately, in opinion. It is not my wish to come here, except for the purpose of transacting this very painful business; and not one word should I say, except what I think is tending to that end. Then am I to understand that you decline to receive this?

6436. We do?—Very good. The next book I will refer to is, "Memoirs of John Abernethy, with a view " of his Lectures, &c., by George Macilwain, Fellow " of the Royal College of Surgeons. Third edition. " London: Hatchard and Company, Piccadilly, 1856." These are the words of Abernethy himself, at page 212: "Mr. Hunter, whom I should not have " believed to be very scrupulous about inflicting suf" ferings upon animals, nevertheless censures Spalan" zani for the unmeaning repetition of similar experi" ments. Having resolved publicly to express my " own opinion with respect to this subject, I choose " the present opportunity to do it, because I believe " Spalanzani to have been one of those who have tor" tured and destroyed animals in vain. I do not " perceive that in the two principal subjects which " he sought to elucidate, he has added any important " fact to our stock of knowledge; besides, some of his " experiments are of a nature that a good man would " have blushed to think of, and a wise man ashamed " to publish, for they prove no fact requiring to be " proved, and only show that the aforesaid Abbé was " a filthy-minded fellow."

At page 99 of the same book I find this: "In the " foregoing . . . . most " alluring science."

6437. Is that last passage Mr. Macilwain's opinion or Mr. Abernethy's?—The former quotation that I read from the book is in Abernethy's own words. This is partly from Abernethy and partly from himself, Mr. Macilwain; most of it from Macilwain.

6438. We have had Mr. Macilwain as a witness here before us, therefore it is not necessary for you to read his sentiments to us from a book?—I do not know, my Lord; you may not have exhausted the subject through Mr. Macilwain; I understood him to say that you did not. At page 101 I read this, "As we have already observed we think it demonstrable."

6439. Whose sentiments are these that you are reading now?—I do not see any inverted commas; therefore if they are not wanting through error, it would be Mr. Macilwain's.

6440. Then we will dispense with them, if you please?—Just as you please. Of course, my Lord, you have the power to receive or reject what you like, I suppose. And that I suppose applies to any other passages giving Mr. Macilwain's opinion.

6441. Yes?—Very good. I will now give the opinion of a man of the very first eminence and who is still with us, Sir William Fergusson.

6442. We have had Sir William Fergusson's evidence; we have already heard his opinion, and we do not wish to hear it therefore through you?—It is not through me. This is evidence which he gave in a court of justice on oath.

6443. We do not wish to receive it?—Very good. He says that he performed experiments once himself, and that he now regrets it. When I had the honour of attending here on a previous occasion, I asked if the Royal Commission could supply the Society for the Abolition of Vivisection (of course it is the object of the Commission to give all information possible on this subject throughout the kingdom) with the Croonian lecture delivered by Professor Ferrier to the Royal Society. As I have stated, there is an abstract published of it by the publishers of the Royal Society; but we made application for the lecture itself, which the society thinks it highly desirable to have.

6444. You have not obtained it?—No. I applied to you for it, but I have not received it.

6444*a*. We have not undertaken to furnish you with information; we are looking to you for information?—That lecture would put me in the way of giving it to you.

6445. Will you proceed with anything which you wish to say to us?—Certainly. Then you will not supply us with that?

6446. We are not possessed of it?—But you have the power to call for books and records to be furnished to the Commission, and I thought that you might supply us with it.

6447. We cannot undertake to supply the society with information, we are looking to you for information?—I imagined you had the power granted to you by Her Majesty to call for that very thing; and then if you did, it would place it in our power to tender it as evidence.

6448. (*Mr. Huxley.*) Has the society applied to Messrs. Taylor and Francis, the publishers to the Royal Society?—Yes.

6449. Did they refuse to sell a copy of their proceedings containing that lecture?—I never said it was in the proceedings. I said there was an abstract of it. The abstract we have; but what I applied for before was the lecture itself and not the abstract.

6450. Has the lecture ever been printed?—I do not know; not that I have heard of.

6451. Have you inquired of the Royal Society?—Of their publishers we have.

6452. Have you inquired at the office of the Royal Society itself?—No; I thought it would be out of the course of business; that they would consider it an intrusion on our part to ask it; and that the publishers would be the proper persons to apply to. If we could get it by applying there we would apply very soon. I suppose you have no intention to convey that it is a fact that we could have it by application?

6453. I have no intention to convey any impression whatever. I have asked you a question, and I now have your answer?—Very good; that is very clear then. I will now quote from the "Edinburgh Medical " and Surgical Journal, Volume 63, Article 1. An " experimental Inquiry into the Pathology and Treat" ment of Asphyxia, by John E. Erichsen, Lecturer " on General Anatomy and Physiology at the West" minster Hospital, London." You smile, my Lord, but I am not aware of anything in that title which should call forth smiles. At pages 16 and 17 I find this——

6454. (*Mr. Erichsen.*) Will you give the date of that, please?—January 1845.

6455. Thirty years ago?—It is none the less true for that, I suppose?

6456. No; but I have a special reason for mentioning it?—"Experiment 9. Three mongrel terriers " A, B, and C, were properly secured in such a way " that their heads might be brought into close appo" sition. A tube, furnished with a stop-cock, was " then introduced into the proximal end of the left " carotid artery of A, and another into that of the " right carotid artery of C. These vessels had pre" viously been ligatured beyond the point at which " the pipes were introduced, so that no hæmorrhage " might occur. The force of the heart's impulse in " the lateral dogs A and C was now measured by the " hæmadynamometer."

6457. (*Chairman.*) I think you are repeating what you read to us on a former occasion, are you not?—

Mr. G. R. Jesse.

20 Dec. 1875.

Not knowingly, certainly. In fact I am certain that I did not read it before. What I was reading on the last occasion was the work of Dr. John Reid, in which he referred to Mr. Erichsen.

6458. But are you going to read to us over again the same thing ?—No, I am not. I am too good a man of business, I hope, to do that. The passage proceeds, "and found to amount to from $4\frac{1}{2}$ to 5 inches " in each of them. A tube, furnished with a stop-" cock, was next adapted to the trachea of the centre " dog B, and a pipe was introduced into the distal " extremities of both its carotid arteries, which were " tied below the point at which the pipes were in-" serted. The animal did not appear in the least to " suffer from the ligature of both these arteries. One " of the jugular veins of the centre dog was then " exposed, and a ligature was passed under it, in " order that it might be punctured, so as to avoid the " occurrence of plethora and apoplexy, when the " carotid arteries of the two lateral dogs were con-" nected with the corresponding vessels of the central " one. The pipes in the carotid artery of A and C " were then adapted, by means of connecting pieces, to " those in the central dog, and were, besides, tightly " tied together, so that they could not slip during the " struggles of the animal. When this arrangement " had been properly and securely made, the trachea " of the centre dog was closed, the jugular vein was " punctured, and the stop-cocks connecting its carotid " arteries with those of the lateral dogs were opened. " As soon as this had been done, the vertebrals of the " dog B (the centre one) were compressed with the " fingers of an assistant, in order that the circulation " through the brain might be confined as nearly as " possible to arterial blood. The centre dog remained " quiet for about a minute and a quarter; it then " began to struggle; and in three minutes all move-" ment had ceased, and animal life was extinct. The " distal extremities of the carotid arteries of the " centre dog were then examined, as they had been " several times during the experiment, and were " found still to pulsate, although somewhat feebly, " from the impulse of the blood sent direct from the " hearts of the lateral dogs. Nearly a pint of blood " had flowed from the jugular vein during the experi-" ment, so that the animal had clearly not died from " plethora. The lateral dogs were both alive, but " evidently enfeebled by loss of blood; and on the " pressure in the carotid artery of one of them being " measured by the hæmadynamometer it was found to " amount to not more than 3 or $3\frac{1}{4}$ inches of mercury. " The centre dog was opened about 10 minutes after " its death, by which time the action of the heart had " entirely ceased." I would go on with more of these experiments, but I think one is, perhaps, sufficient; but I wish it to go down in evidence that others are detailed in the same journal.

6459. (*Mr. Erichsen.*) Those experiments were made by me, in conjunction partly with Dr. Sharpey, from a grant. We were appointed in the year 1842 by the British Association for the Advancement of Science to inquire into the subject of asphyxia. A grant of money was given by that Association for that purpose. Those experiments were made for the Association and reported to the Association, and they were considered of sufficient importance by the Royal Humane Society for them to award to me their large Fothergillian gold medal, the only time that it has been awarded, except in one instance, and that was to the present Sir James Kay Shuttleworth, for other experiments on the same subject. Are you aware of those facts? —No. I was not aware of all of them. I think I was aware of one, but I cannot be sure till I look further at this one which I referred to just now. I see that this is a report laid before the British Association; that is all that I know in regard to what you have just stated. But what you have just stated does not alter the views of our society about these experiments at all; it is only an additional proof of them. I think they are experiments from which conclusions were drawn which Dr. Reid afterwards, from his experiments, differed from. I think it will be found in my previous evidence that they led to inaccurate results. Bayle, "Dictionaire Historique et Critique de Pierre Bayle. Paris, 1820;" 12th volume; article, "Rorarius;" page 593; note C. I do not wish to appear to try to get in evidence of the nature which the Commission has declined to receive. The Chairman knows Bayle's Dictionary very well, no doubt. I am not aware if Bayle was a vivisector, but he has been quoted by Lecky, on the subject of vivisection, in his "History of European Morals."

6460. (*Chairman.*) You can put in the reference, cannot you?—Yes, I can do so; but we prefer reading the passage; it is very short.

6460a. Will you put in the reference, if you please? —As I have stated, it is at page 593; note C; article, "Rorarius."

The next book to which I will refer is the "Hand-" book of Physiology, by William Senhouse Kirkes, " M.D., edited by W. Morrant Baker, F.R.C.S., Lec-" turer on Physiology and Assistant Surgeon to " St. Bartholomew's Hospital; Surgeon to the Eve-" lina Hospital for Sick Children. Eighth edition. " London: John Murray, Albemarle Street, 1872." We produce this work in evidence as a handbook placed in the hands of young men, and to show what teaching they receive,—teaching which, in the opinion of our society, tends to demoralise their minds and to render them inhuman. At page 182 I find this: " Some experiments, performed by Dr. Kellie, ap-" peared to establish the correctness of this view. " But Dr. Burrows, having repeated these experi-" ments and performed additional ones, obtained dif-" ferent results. He found that in animals bled to " death without any aperture being made in the " cranium, the brain became pale and anæmic, like " other parts. And in proof that during life the " cerebral circulation is influenced by the same " general circumstances that influence the circulation " elsewhere, he found congestion of the cerebral " vessels in rabbits killed by strangling or drowning; " while in others killed by prussic acid, he observed " that the quantity of blood in the cavity of the " cranium was determined by the position in which " the animal was placed after death, the cerebral ves-" sels being congested when the animal was suspended " with its head downwards, and comparatively empty " when the animal was kept suspended by the ears." We think that a book of this kind is calculated to make these young men try these so-called experiments in their lodgings and elsewhere. I fancy it is pretty well known what they do do to a certain extent in that way.

6461. Before you go any further, will you allow me to ask you how many pages there are of the book altogether?—There are 835 pages.

6462. You do not propose to read any large part of them, do you?—No; they are short passages that I propose to read.

6463. In your opinion, have they any special appropriateness to this inquiry?—Yes, decidedly.

6464. You have already referred to the whole book as objectionable in your view?—When you say the whole book, there may be parts of the book which are exceedingly proper. If it tells you how to set the broken leg of a man, for instance, I should consider that quite the right thing.

6465. But I understood you to say, a little while ago, that you referred to the whole book?—I do, as far as it is imbued with that principle. I am not going to condemn every page in the book. The next passage I will read is at page 206: "The great force of the " inspiratory efforts during apnœa was well shown in " some of the experiments performed by the Medico-" Chirurgical Society's Committee on Suspended Ani-" mation. On inserting a glass tube into the trachea " of a dog, and immersing the other end of the tube " in a vessel of mercury, the respiratory efforts during " apnœa were so great as to draw the mercury four " inches up the tube. The influence of the same " force was shown in other experiments, in which the

Mr. G. R. Jesse.

20 Dec. 1875.

"heads of animals were immersed both in mercury and in liquid plaster of Paris. In both cases the material was found, after death, to have been drawn up into all the bronchial tubes, filling the tissue of the lungs." Then at page 229 I find this: "In some experiments performed by a committee appointed by the Medico-Chirurgical Society to investigate the subject of suspended animation, it was found that, in the dog, during simple apnœa, *i.e.*, simple privation of air, as by plugging the trachea, the average duration of the respiratory movements after the animal had been deprived of air was 4 minutes 5 seconds, the extremes being 3 minutes 30 seconds and 4 minutes 40 seconds. The average duration of the heart's action, on the other hand, was 7 minutes 11 seconds, the extremes being 6 minutes 40 seconds and 7 minutes 45 seconds. It would seem, therefore, that, on an average, the heart's action continues for 3 minutes 15 seconds after the animal has ceased to make respiratory efforts. A very similar relation was observed in the rabbit. Recovery never took place after the heart's action had ceased." Then lower down on the same page it says: "In proof of the correctness of this explanation, it was found that when two dogs of the same size, one, however, having his windpipe plugged, the other not, were submerged at the same moment, and taken out after being under water for two minutes, the former recovered on removal of the plug, and the latter did not."

6466. You quote these as instances of experiments described in that book which you consider to be very cruel experiments, do not you?—I do consider them very cruel.

6467. I mean that is the purpose of your quoting them?—That is partly the purpose, and also what I before stated, to show how the young are being educated.

6468. But are those examples fair samples of what you wish us to gather from that book?—What do you mean by "fair samples?"

6469. What I mean is, do they sufficiently indicate the sort of conclusion which you wish us to draw from the contents of that book?—I do not exactly see what you are leading up to.

6470. What I am pointing at is this: I want to know why we should have any more examples read to us when the whole book has been already put in by you as evidence?—But I do not put in the whole book in that way. I say it is imbued with that, but I do not say that every page contains cruelties.

6471. But do you mean to read to us every page that does?—No, I do not; I have taken a selection.

6472. Will you be so good as to be limited in your selection?—I am so.

6473. We think that you had rather forgotten that our time, and your time, and all time, is limited?—You do me an injustice in that. I do not know as to all time being limited; that remains to be proved; but as to my time, I am quite aware of that.

Then at page 244 I find this: "Walther found that rabbits and dogs, when tied to a board and exposed to a hot sun, reached a temperature of 114·8° F., and then died. Cases of sunstroke furnish us with similar examples in the case of man; for it would seem that here death ensues chiefly or solely from elevation of the temperature." A little lower down on the same page I read this: "From experiments by Walther, it appears that rabbits can be cooled down to 48° F. before they die, if artificial respiration be kept up. Cooled down to 64° F. they cannot recover, unless external warmth be applied together with the employment of artificial respiration. Rabbits not cooled below 77° F. recover by external warmth alone." Then come some experiments extracted from Magendie, Tiedemann, and Gmelin,—experiments on dogs, but I do not think it is necessary to read them. We have abstained as much as possible from going upon the continent; we have got enough at home. I should like a note, however, taken that it is in the book. Then at page 250 I find this: "One of the most notable effects of starvation, as might be expected, is loss of weight, the loss being greatest at first, as a rule, but afterwards not varying very much, day by day, until death ensues. Chossat found that the ultimate proportional loss was, in different animals experimented on, almost exactly the same, death occurring when the body had lost two fifths (40 per cent.) of its original weight." At page 251, "The effect of starvation on the temperature of the various animals experimented on by Chossat was very marked." Then at page 295, under the heading, "Digestion of the stomach after death," I find this passage: "This phenomenon is not unfrequently observed in post-mortem examinations of the human body; but, as Dr. Pavy observes, the effect may be rendered by experiment more strikingly manifest. 'If, for instance,' he remarks, 'an animal, as a rabbit be killed at a period of digestion, and afterward exposed to artificial warmth to prevent its temperature from falling, not only the stomach, but many of the surrounding parts, will be found to have been dissolved,'" and so on. Lower down on the same page I read, "It is only necessary to refer to the idea of Bernard, that the living stomach finds protection from its secretion in the presence of epithalium and mucus, which are constantly renewed in the same degree that they are constantly dissolved, in order to remark that this theory has been disproved by experiments of Pavy's, in which the mucus membrane of the stomachs of dogs was dissected off for a small space, and, on killing the animals some days afterwards, no sign of digestion of the stomach was visible." So that there is the vivisector of Paris, at least one of them, disproved here by the vivisector in London, according to this book. No man can go through the works of these vivisectionists without being very very frequently struck with the simple fact, that one man lays down a theory and a succeeding man overthrows it. And I would take this opportunity respectfully to suggest, on the part of the Society which I represent, that Her Majesty's Commission might do well to call forward some of these vivisectionists, and ask them what it is they have discovered. Let them define it; and then call forward other vivisectionists and competent professional men, and take their opinion whether they have discovered anything or not.

Then at page 297 I find this: "Dr. Pavy's theory is the best and most ingenious hitherto framed in connexion with this subject, but the experiments adduced in its favour are open to many objections, and afford only a negative support to the conclusions they are intended to prove. The matter, therefore, can scarcely be considered finally settled." On page 386 I read this, "The same fact was illustrated by some experiments of Dr. Baly, in which, having in salamanders cut off the end of the tail, and then thrust a thin wire some distance up the spinal canal, so as to destroy the cord, he found that the end of the tail was reproduced more slowly than in other salamanders in whom the spinal cord was left uninjured above the point at which the tail was amputated." At page 559 there is this passage: "The most probable account" (so I suppose there are others which are probable, but this is "the most probable") "of the particular functions which the branches of the pneumo-gastric nerve discharge in the several parts to which they are distributed may be drawn from Dr. John Reid's experiments on dogs. They show," and so on. I do not know whether that refers to the experiments that Mr. Erichsen mentioned.

At page 525 I find this: "The physiology of the cerebellum may be considered in its relation to sensation, voluntary motion, and the instincts or higher faculties of the mind. It is itself insensible to irritation, and may be all cut away without eliciting signs of pain (Longet), yet, if any of its crura be touched, pain is indicated, and, if the

Mr. G. R. Jesse.

20 Dec. 1875.

" restiform tracts of the medulla oblongata be " irritated, the most acute suffering appears to be " produced. Its removal or disorganization by " disease is also generally unaccompanied with loss or " disorder of sensibility. Animals from which it is " removed can smell, see, hear, and feel pain, to all " appearance, as perfectly as before (Flourens, Ma- " gendie). So that, although the restiform tracts of " the medulla oblongata, which themselves appear so " sensitive, enter the cerebellum, it cannot be regarded " as a principal organ of sensibility."

At page 335 I read "Instead of adopting Bernard's " view, that normally during life glycogen passes as " sugar into the hepatic venous blood and thereby is " conveyed to the lungs to be further disposed of, " Pavy inclines to believe that it may represent an " intermediate stage in the formation of fat from ma- " terials absorbed from the alimentary canal."

As I have already said to-day, if we have not succeeded in convincing the minds of the Commission in regard to our opening statement being correct, we are prepared to go on with further documentary evidence, but if we have been fortunate enough to do so, of course we need go no further. I have given to-day the opinion of Sir Charles Bell, and I think nothing could be in stronger words, and nothing could come from a man of greater eminence.

6474. I am afraid you misunderstand our relative position in this particular,—that we came here to ask you questions, and not to answer questions put by you?—I am aware of that; I stated so on a previous occasion.

6475. Now if you will proceed to finish what you have got to say, we are quite ready to hear you?—You do not say whether you are convinced or not, but in the opinion of the society we have most fully and amply established the position which we took up; and if we have not produced conviction by the evidence which we have tendered from the works of vivisectors themselves and other competent men, professional men and others, we think that no amount of evidence could do it, and therefore of course it would be unnecessary to proceed. I will therefore, if you will allow me, conclude the evidence which I have tendered to Her Majesty's Commission, with some remarks from the society itself, which is for the abolition of the very practices upon which Her Majesty's Commission is sitting to inquire. The mere reading of these cruelties creates disquietude and distress of mind, indignation, abhorrence, and in some persons even illness of body. Thousands of letters have been received by the society for the abolition of vivisection, from people of education, testifying the above. The feeling is not confined to the upper and middle classes of this nation. The Society for the Abolition of Vivisection would, had it been allowed by the Royal Commission to do so, have read some of these letters in evidence. Such strong opinion and vehement feeling could hardly have been evoked without a strong exciting cause, and as an illustrious French writer, a man of science, says, "The heart has its arguments as well as the understanding." It is the voice of nature which exclaims against these inhuman, these unnatural, these, in some cases, bestial tyranies perpetrated by man on his helpless and unoffending fellow creatures. Can deeds be right which call forth such intense feeling against them from men and women of sense and respectability? Even if any discoveries in knowledge had been extorted and wrung out by torture from these unhappy and innocent victims (and this is denied by competent authorities like Sir Charles Bell and several others), such discoveries are gained by injustice, and being so, will ultimately prove profitless and worse than profitless to the human race. Dishonesty takes the short cut to everything. It seems easier to steal than to earn. But the homely adage is true, "Ill gotten wealth seldom prospers." Samuel Johnson said of these practices that they extinguish those sensations which give man confidence in man, and make the physician more dreaded than the gout or stone. Were the so-termed discoveries made by the torturers of animals far greater than they are, the physical gain to the human race can never balance the moral evil generated by their cruelties. Science can never make an adequate gain by practices which demoralize the minds of those who perpetrate them, and who moreover at last sometimes take, as a distinguished surgeon, Sir Philip Crampton, has said, an insane gratification of cruel lust in perpetrating what has been called the "crime of fools." This groping with a lanthorn and a fork in the gutter of a shambles can never elevate mankind. To torture an innocent creature to death, be that creature man or other creature, is a wrong, and in the latter instance a most dastardly wrong. Those beings who stretch animals on the rack and inflict countless ingenious refinements of agony on creatures which they get within their power would, it seems probable, do the very same to their own particular species did they dare to do so. It has been done and may be done again. At Montpellier physicians dissected criminals alive, and even in this country suspicions connected with baby farms have arisen. We are told that the bodies of dead animals in a hospital have been packed up with the bodies of anatomised subjects, in the coffins of the latter. The money given by the benevolent public to hospitals for the cure of patients appears to be to some extent misappropriated. Money given to cure the sick, to assuage pain, is expended in inflicting torture on animals. The yearly prospectuses issued by the authorities of the medical schools are evidence which cannot be successfully denied; and are not these practices enjoined by the examining and licensing bodies and council of education? A practice wanting in dignity, as it is carried on with closed doors, is contrary to law, and demoralizing to thousands of students. I might mention, perhaps, the Brown Institution and Guy's Hospital as cases in point. This moral contagion may well spread, and what has been done in America may be done here, and the very poor and friendless be experimented on. No hard and fast line can be drawn, we are told, between man and animals, as to his physical nature. Can such a line be drawn morally? We say no. Will any vivisectionist propose to torture to death on the score of utility idiots, foundlings, paupers, or even criminals? How then can it be justifiable to torture an animal? Not on the score of mind; for an animal has mind, an idiot or an infant has none. The plea of knowledge to be obtained is no excuse; the good of humanity is no excuse. We have more knowledge already than we use for good. Every man, more or less, knowingly does wrong. A moral reform and the diffusion of knowledge are required far more than increase in knowledge. What practical follies are still generally practised by society! Look at the moral injury and the waste of wealth by drink. Look at the cruel and silly bearing rein. If every man always spoke the truth, and tried to do as he would be done by, the happiness of the world would be vastly increased, almost infinitely more so than by any physical discoveries which have ever been made. Edmund Burke even said that the manners of a people were more conducive to its happiness than were its laws. "The gods are just, and of our pleasant vices make instruments to scourge us." No scientific armour will ever protect mankind from their thongs, any more than from the sting of conscience and the agonies of remorse. Folly, vice, ignorance, dirt, and selfishness create disease. To torture animals to escape the natural penalty of viciousness is ridiculous. It is striking at the effect and not the cause. The degradation of mind which accrues from these cruelties has been well proved in the instances of Spalazani, Brachet, &c., and we believe by the French, as displayed in their unnatural experiments on hybridism. Such must inevitably tend to blunt the moral sense, and lead to the ultimate destruction and downfall of a nation. The words of an illustrious writer apply to vivisectors, "Man has a glimmering of Heaven's light. He calls " it reason, and uses it only to be the most brutal

Mr. G. R. Jesse.

20 Dec. 1875.

"of brutes,"—the words of the most intellectual of the Germans. Man is cruel. Read his history, written by himself. Southey termed it a "Chronicle of crime." Shakspere says, "The earth is wronged by man's injustice." Thomson says, "Oh, man! Tyrannic lord. "How long, how long shall prostrate nature groan "beneath thy rage awaiting renovation?" Pope called him "Foe to nature;" and Burns wrote of him

"But man, to whom alone is given
"A ray direct from pitying Heaven,
"Glories in his heart humane
"And creatures for his pleasure slain."

And again—

"Plumes himself in freedom's pride,
"Tyrant stern to all beside."

The conduct of the ruthless Spaniards towards the unoffending races of America is a case in point. They considered them as animals, and the Pope, to protect them, issued a bull asserting that they had souls, and were not to be treated as mere beasts of burden. The negro was regarded very much in the same way. And dire as were the cruelties of the slave ship, the "Legrees" of these poor wretches have been equalled by the torturers of the dumb. In the laboratory of the vivisector,—screams, looks for mercy, appeals for compassion, cries for help, convulsions of agony, are disregarded and never heard beyond its walls. The vivisectors have disclosed awful scenes of cruelty; but what are those which they have never told? All this iniquitous torture of our weaker fellow creatures tends to the incarnation of evil, namely intellect divorced from moral principle. How can mercy form part of religious instruction in the face of such education as is conveyed in Professor Huxley's "Elementary Physiology for Boys and Girls"? The practice of vivisection strikes some minds as unnatural; as absurd as it would be for an analytical chemist to pick to bits and test and scrutinise under the microscope a Titian or a Turner in the hope of discovering their systems of colouring and design. Nevertheless these purblind gropers in the entrails of animals, who begin by theft (for we hear they obtain their miserable victims from some slave in Seven Dials or St. Giles's, or the purlieus of Leadenhall Market, who brings the poor beasts, under cover of the night, to their laboratories; they thus consort and shake hands with some of the basest of mankind),—who begin by breaking the law, doing these things under the cover of secrecy,—go on day after day, month after month, year after year, torturing and murdering, callous and heartless, without pity, love, or fear, and are capable (their lives prove it) of tying down and torturing (were it possible to prevent its taking refuge in death) the same suffering creature for 50 consecutive years. Whether they torture 50 for one year apiece, or one for 50 years, what is the difference? Is this justifiable on any pretext whatever? Such beings are more detestable than the other bigots of the middle ages, and (as we are informed the late gentle and gallant Sir Hope Grant stated) "deserve to be put to death." Too many physiologists seem to fancy that the remotest prospect of a discovery useful to human beings will justify the infliction on the lower creation, as it is called, of the most excruciating pain. That position we believe to be untenable before a tribunal to which we are all amenable, however the matter may stand in a court composed of our human fellow-creatures. We would earnestly request the Commissioners to make especial inquiries of notorious vivisectors (I shall repeat myself a little here, but very little) with regard to what they themselves individually have discovered by means of vivisection; not what they affirm has been discovered, but what each one of themselves has personally found out of benefit to the human race; the opinion of independent witnesses being also ascertained as to whether the so-termed discoveries are really discoveries or not; and, moreover, whether in their opinion such discoveries, if they are esteemed so by professional and other competent and impartial witnesses, might not have been otherwise arrived at, or the so-called necessity for them be rendered nugatory by obedience to the moral and physical laws of God and Nature. The Society for the Abolition of Vivisection has no connexion with the Society for the Prevention of Cruelty to Animals of Jermyn Street, but deeply regrets the supineness of its executive, for years past, on the cruelties of vivisectors. Neither has it any connexion with the new association termed the "Society for the Protection of Animals liable to "Vivisection," as the object of our society is not permission, but the total prohibition and suppression of the torture of living animals. Any scheme for permitting and then "regulating" scientific cruelties the Society for the Abolition of Vivisection deems to be doing evil in the fallacious hope that good may come; and it denounces strongly all legislation that will license cruelty under whatever pretence, or repeal in any degree the Magna Charta of Animals, 12 and 13 Victoria, chapter 92, as to do so is palpably protecting the wrong-doer, and actually diminishing the protection to the animal creation which the existing laws of England afford. The regulation by law of cruelty is an unjustifiable and retrograde movement. Better let the law remain exactly as it now is, and enforce it, than enter into any compromise with those who advocate the infliction of systematic and unnumbered miseries in the name of science, on the helpless, dumb creation of our Common Parent. High medical and physiological authorities have given it as their opinion that researches carried out on the mangled or tortured bodies of living animals are of no value, or even worse than useless, inasmuch as they actually lead into error. From Celsus to Nélaton, eminent physiologists, medical practitioners, and others have condemned vivisection. Gall, Cuvier, Sir Charles Bell, Sir Philip Crampton, Dr. John Reid, Golding, Dr. Hull, McWhirter, Macilwain, and numbers of other scientific, medical, as well as literary men of the highest intellect endorse these views as to its uselessness. Sir William Fergusson recently stated on oath, —"I do not perform experiments myself; formerly I "did; but I now regret them." It is a belief with many persons, including even medical men, that Harvey discovered the circulation of the blood, Hunter the cure of aneurism, and Bell the nature of the nervous system by vivisection. The belief is erroneous. The Society for the Abolition of Vivisection states it as its conviction that the present time is premature for legislation, inasmuch as the nation is but slightly informed of the existence, extent, and nature of vivisection. Till that be effected there is no base of operations, no fulcrum whereon to place the lever that can move Parliament. The vivisectionists are wise in pushing on the parliamentary conflict ere a public opinion has had time to grow and spread and be a power. We want first and most a wide diffusion of the horrid details. We should then gain an overwhelming force. This is in some measure proved by thousands of letters received by the abolition society from various parts of the kingdom and from abroad, breathing the utmost sorrow, indignation, horror, and disgust at the atrocities published by the society, atrocities perpetrated in England and Scotland, and the accounts of which have in great measure been extracted from the books of vivisectors themselves. As to the assertions which have been made that the society's statements have been hastily prepared, such assertions not only are incorrect, but utterly contrary to the truth, and calculated to give a most erroneous impression. No statements made by the Society for the Abolition of Vivisection have been otherwise than accurate. When challenged, they have been made good, and the published correspondence with Dr. J. Crichton Browne, Professor Ferrier, Professor Rutherford, Sir John Rose Cormack, M.D., and that in the "Standard," "Daily News," "Morning Post," "Echo," "Globe," "Jewish Chronicle," "Scotsman," and other newspapers, has worsted every antagonist who has met the society openly in the field. As to Lord Henniker's bill for licensing vivisection, it had neither the sympathy nor the support of our society, and we so stated in the "Times." The committee of the Society for

Mr. G. R. Jesse.

20 Dec. 1875.

the Abolition of Vivisection earnestly appeals to those who prefer to protect the dumb creation to the uttermost, rather than adopt specious remedies for the prevention of cruelty, or embrace any mischievous projects of expediency; and so long as the committee continues to receive the support of the public and is encouraged to persevere, it will oppose to the uttermost all compromise with these barbarous and demoralizing outrages on nature on the sentient creatures of our Almighty Father. To this end the committee will neither ask nor accept anything less than a total prohibition of vivisection, or the mangling living animals with saws and dissecting knives, and subjecting them to other inhuman, elaborate, and prolonged sufferings. Those are the remarks which I had to make; and I wish to say this in conclusion: I had not an opportunity given me to answer a question put on a previous occasion here by the author of an educational book for the young, termed "Lessons in Elementary Physiology." The question was, "What was the object in reading passages from it?" I am desirous on the part of our society of answering that question. Do you wish me to answer it?

6476. I understood you wished to answer it?—I do wish to answer it.

6477. Will you be so good as to do so?—The object is (as the society has a strong aversion to the book as dangerously qualified to vitiate and demoralize the minds of the young), to prove from the book itself how vivisection is spreading through the land, and how the rising generation in this kingdom is being actually taught vice, and that vice the worst, namely, cruelty, (Cowper says, "the most devilish of them all,") by the infliction of torture on domestic animals; moreover to publish to the world how callous a member of the Commission is which has been expressly appointed by Her Majesty to inquire into the extent of these cruelties.

6478. You have made these statement on behalf of the society, is that so?—Yes.

6479. Were they adopted at any meeting of the society?—I do not think I am called upon to answer questions in regard to the internal arrangements of our society.

6480. You decline to do so?—I do.

6481. (*Mr. Forster.*) You are aware that you have stated over and over again in the course of your evidence that you speak on behalf of the society?—I do; I am the honorary secretary.

6482. Have you read to any committee of the society the statements that you have made to-day?—I will answer your question in the same way in which I just answered it to Lord Cardwell. In regard to the private arrangements of our society I decline to answer questions.

6482*a*. Do I rightly understand you to decline to give us any information as to what extent, and in what manner, the society is responsible for what you say?—I have given my answer already; I decline to say anything further.

6483. (*Chairman.*) You decline to mention the name of any other party than yourself who is responsible for these statements?—You have put the question to me, and I have answered it.

6483*a*. (*Mr. Huxley.*) I must put a question of the same kind, because I am familiar with the organization of societies, and know the circumstances under which societies of credit and authority act. It is for the witness to make up his mind whether he will answer the question or not, but I shall put a question, or rather a series of questions to him. My first is, when was the society instituted, answer that?—I have no objection to answer that. I cannot say for certain, but you will see the advertisement in the "Times," if you look back.

6484. I have asked you, as honorary secretary for the society, when the society was instituted?—I believe that will tell you better than I can, for I do not remember the date.

6484*a*. Was it this year or the year before?—This year.

6485. Has any general meeting of the society ever been held?—What do you call a "general meeting?"

6486. Every person who understands the organization of respectably-conducted societies —— ?—You mean to infer that ours is not one?

6487. I do nothing of the kind. On this occasion I must ask you to be so good as to confine yourself to the grammatical construction of my words?—I confine myself to the grammatical construction of your words, and the natural inference from them. I have met with something already here, and will not submit to anything further.

6488. I have now to inform you that I put these questions to you for the purpose of enabling you to understand that I have no intention of suggesting anything whatever about your society, except that it may be conducted with propriety so far as I know; but I desire to learn, not only for my own information, but for that of the public, which is very much interested in this matter, whether this society, in the name of which you have over and over again solemnly professed to act, and of which you have declared yourself formally to us to be the representative, is a society organized in the manner in which all respectably-organized societies are organized. I therefore ask you the question whether you have ever had a general meeting?—I do not know what you mean by "how respectably-organized societies are organized."

6489. I am perfectly familiar with the organization of all the most important scientific societies in London; I call those respectable societies; and I wish to ascertain whether your society, the respectability of which I do not doubt, is organized in the same fashion?—I do not know how those are organized; therefore it is impossible for me to tell you.

6490. I now ask you whether you have ever had a general meeting of your society?—We have had a meeting of the committee, some members of it.

6491. (*Chairman.*) Have you any objection to state whether the society has ever had a general meeting?—I have answered the question. I said that there had been a meeting of some members of the committee.

6492. Have you any objection to say how many?—Yes, I have, because I think you are getting very inquisitorial in regard to the private concerns of the society, with which I do not see (I speak with all courtesy) that you have anything to do.

6493. You consider that the constitution of your society is a matter of private concern, with which the public has nothing to do?—I have given my answer.

6494. (*Mr. Forster.*) You have not answered that question?—I think I did.

6495. (*Chairman.*) My question was this: You consider that the constitution of your society is a matter of private concern, with which the public has nothing to do?—Yes.

6496. (*Mr. Huxley.*) I now would ask by whom the committee was appointed?—I think that all this is very idle talk. I do not see what it concerns anybody how the committee was appointed at all.

6497. Is that your answer to my question?—Yes, it is. You can see the names of the committee advertised in the papers, at least they have been very frequently; and the committee which was first appointed still remains the committee of the society; and I must request you, if you have anything to say similar to that which you have just been saying, to communicate with them. Perhaps you had better write to Sir George Duckett, Bart., Weald Manor House, Oxfordshire.

6498. I wish to have your answer or refusal?—I have given you my answer, and have nothing else to say.

6499. Is there any treasurer to the society?—Well, what is that to you? You are not a subscriber to it.

6500. Have the accounts of the society ever been audited?—I really shall not answer any more questions of this sort. I beg you will take that answer once for all. I consider them exceedingly inquisitorial. You have no more right to put questions to

Mr. G. R. Jesse.

20 Dec. 1875.

me like that, than you have to ask what money I have in my pocket, or what I am going to have for dinner.

6501. (*Chairman.*) You have given us on several occasions what you have told us to be the views of the society?—Yes.

6502. Do I correctly understand you that now, when we inquire what the constitution of the society is, you think it an inquisitorial mode of examination, and decline to give an answer?—Most decidedly.

6503. (*Mr. Huxley.*) The only further questions that I have to put are questions on which I am sorry to occupy the time of the Commission ——?—Do not do it then.

6504. (*Chairman.*) There must be a certain amount of courtesy on your part. You have experienced a great deal of patience from us, and you must now be so courteous, and so mindful of the duties of a witness, as to listen to the questions of a Commissioner, and not interrupt him?—Allow me to answer that remark. I do not think I have laid myself open to any such remark as you have just made about courtesy, however it might apply to the other side. And as to one of the Commissioners, he said that he was sorry to take up your time with asking a question. Then why should he do it? My time is of some consequence as well as that of other persons; and when you speak of me coming here as if I was come here as a matter of favour, I come here to better inform you. Her Majesty's powers granted to you expressly state that; and I ought to be received here, and every witness, with the greatest courtesy. We are here to discharge a public duty, not here for pleasure or for profit. I come here not only at inconvenience to myself, but at positive risk to my health, as I have told you before.

6505. What you are asked to do is to listen to the end of a question before you answer it, and not to interrupt it with an answer?—I should under ordinary circumstances, but he stated that he was wasting your time, or other words to that effect, by asking it.

6506. (*Mr. Huxley.*) If the witness had waited till the end of my question, he would have heard that, in my judgment, it is a waste of time to put the question which I am about to put, but that, as my silence may be misinterpreted, I proceed to put that question. Now, in order to remove this matter entirely from the personal region into which it might drift, I may remark, that the witness referred just now to certain "Lessons in Elementary Physiology, by Thomas H. "Huxley." I wish to know upon what grounds the witness bases the statement which he made at the end of his remarks, that this book recommended the practice of vivisection to young people in schools?—My former evidence will answer that, in which I read quotations from that book.

6507. In those quotations there is nothing but a description of certain experiments, and of the results which followed from them, given with the intention, as is obvious from the book itself, of impressing the results of those experiments, which are of great importance, distinctly upon the minds of the students. So that on the face of it it does not appear that the account of such experiments encourages vivisection. Is there any distinct encouragement in the book of vivisection, anything beyond what you have just cited?—Most distinctly, I think.

6508. In what passage?—Those that I have quoted.

6509. A passage is quoted in the evidence which you have already given to this effect: "For the "purpose of acquiring a practical though elementary "acquaintance with physiological anatomy and his- "tology, the organs and tissues of the commonest "domestic animals afford ample materials." Is that, in your judgment, an encouragement to vivisection?—You must take it all together. The whole of it certainly is.

6510. I request a distinct answer to that question?—I would like to have a proof of my former evidence before me. I have not yet examined that proof, and therefore I do not know whether it is accurate or not.

(*The proof was handed to the witness.*)

6511. The passage in your evidence to which I call your attention is this: "In the preface to the second "edition I find, 'As the majority of the readers of "'these lessons will assuredly have no opportunity "'of studying anatomy or physiology upon the "'human subject, these remarks may seem dis- "'couraging. But they are not so in reality. For "'the purpose of acquiring a practical though "'elementary acquaintance with physiological ana- "'tomy and histology, the organs and tissues of the "'commonest domestic animals afford ample mate- "'rials.'" Do you consider that passage to inculcate or suggest vivisection?—It gives a strong impression to that effect, and coupled with the extracts which were taken from the work elsewhere they certainly have left a most decided impression upon me that that book does what I say.

6512. Is vivisection of the smallest use in the study of anatomy?—As I said, I came here at the request of the Commission; I did not tender myself as a witness; and, as I first stated, I do not attend here as a medical or scientific witness; and I do not wish to be entangled by any professional questions of that sort, or any others. Whether vivisection is a benefit to medicine or not, I leave abler men to decide. I have given you the opinions of many able men, who say that it does not do good, on the contrary, that it propagates error.

6513. You have based a charge here upon a definite passage in the work of this writer. You are therefore bound to show that you understand what the language, which you charge with a certain effect, means. I now put to you a question for the purpose of inquiring whether you really do know what it means; and I ask whether there is anything there to show, and whether you hold the opinion, that vivisection is of any good for anatomical purposes purely?—That I consider is a question not to the point.

6514. I ask you if you know what histology means?—I am not going to answer any professional questions, as I have said already.

6515. (*Chairman.*) But you have made a charge against this book, that it has a certain tendency, and the object of these questions is to discover upon what that charge rests?—It rests upon these passages.

6516. Then, to push it a little further, do you consider that anatomy has anything to do with experiments upon living animals?—As I said before these professional questions I must decline to answer. I stated (I must say it over again), when I acceded to the request of the Royal Commission to attend here, that I should do so not as a medical or scientific witness. Now that question is a question for a medical or scientific witness.

6517. No, what I want to know is simply this. A charge has been made by you against the writer of that book?—Most decidedly.

6518. You have quoted certain extracts as proving that charge?—Most decidedly.

6519. You are therefore asked whether you put a certain construction upon those extracts?—I do.

6520. You understand those extracts as recommending experiments upon living animals?—Most decidedly.

6521. And it was because you understood them as meaning experiments on living animals that you condemned them?—Most decidedly.

6522. If therefore they should not have that meaning, I presume your condemnation would fall to the ground?—You ask me what I consider to be an impossibility. It struck my mind as plainly as anything can do, that that book certainly does advise young people to make experiments upon living domestic animals; and I do not think that any fair and candid man of common sense can think otherwise.

6523. That is the ground upon which the charge

Mr.
G. R. Jesse.

20 Dec. 1875.

is rested ?—Yes, most decidedly; the charge is made upon the book itself.

6524. (*Mr. Huxley.*) The second passage which is quoted is this (I will not read the whole of it, because the first is quite sufficient for my purpose). "If when the cord is cut across in an animal, the " cut end of the portion below the division or away " from the brain be irritated, violent movements of " all the muscles supplied by nerves given off from " the lower part of the cord take place, but there is " no sensation." Do you think that is evidence that I would have encouraged a young person to make that experiment ?—I do not want any wire-drawing about it; take the thing in the full. You have had my opinion upon it, upon all the passages put together.

6525. I take that passage, and ask you whether you consider that is evidence that I wished to encourage young persons in vivisection ?—If that is one of the passages which I quoted on a previous occasion, I quoted it with that view, and every one of them.

6526. Now then I will take you, if you please, to a passage which you have not quoted out of the same work. The passage is at page 12 of the 5th edition, and runs thus: "If the upper arm of a man, whose " arm is stretched out, be tightly grasped by another " person, the latter, as the man bends up his fore-" arm, will feel a great soft mass, which lies at the " fore part of the upper arm, swell, harden, and " become prominent. As the arm is extended again " the swelling and hardness vanish. On removing " the skin, the body which thus changes its con-" figuration is found to be a mass of red flesh " sheathed in connective tissue." Are you of opinion that that passage suggests that boys and girls should remove the skin from one another's arms ?—I do not know. I never thought of it before. I should like to take it home and look it over.

6527. The book is accessible to you. I now take you to page 16 of the same work. "Let any person " in the erect position receive a violent blow on the " head, and you know what occurs. On the instant " he drops prostrate, in a heap, with his limbs relaxed " and powerless." Do you think that that is an encouragement to boys and girls to knock one another on the head ?—I do not know. It has rather a tendency that way, I should think, if they are experimentally inclined.

6528. (*Mr. Erichsen.*) You made a statement with regard to the expenditure of funds of hospitals, about which I should like to have some definite information. You stated that money given to hospitals to cure the sick is expended to torture animals. That is the substance of what you stated ?—What I said was that money given by the benevolent public to hospitals for the cure of patients appears to be to some extent misappropriated. Money given to cure the sick, to assuage pain, is expended in inflicting torture on animals.

6529. Will you give me a single instance in which that money has been so misappropriated ?—If you get these prospectuses to which I allude, issued by the authorities of the medical schools (which you know, of course, very well) you will find statements as to experiments being performed on living animals.

6530. Do you believe that the money required for those experiments comes out of the funds of the charity ?—That is the impression that I have, certainly, and that many other people have.

6531. Are you aware that the funds expended by the medical schools for the maintenance of those medical schools, for every purpose connected with experiments in those medical schools, is paid out of the fees of the students belonging to those schools, and that those constitute funds totally distinct from those that are appropriated to the charity and that are subscribed by the public to the hospital as a charity ?—I do not understand you to say that, taking one of those prospectuses (I have not got them in my mind at this moment) you call in question that it is so as to experiments upon living animals. You see the name of Dr. so and so, and then it says that experiments will be performed on living animals, to show the action of the heart, or something or other. Now, do I understand you to say that the money which pays for the animals that are provided for that purpose does not come from the funds of the hospital ?

6532. I want you to give me an instance in which it does. You state broadly that the funds are misappropriated, and I ask you to give me a single instance. No man can make a general sweeping charge against all the medical charities of this country without, I presume, some definite ground to go on; and I want you to tell me the ground on which you go when you make that sweeping charge against the hospital authorities of this country ?—The statement is made upon the strength of prospectuses or whatever is the term for them—yearly prospectuses of these hospitals, in which it is stated (it has been so in several cases, though I think they have left them out of last year's, I know it has been so in one of them, where the statement appeared before they have taken care to leave it out) that experiments are performed on living animals.

6533. (*Chairman.*) But have you any fact to state which bears out the assertion that money contributed for the relief of the sick is applied to the purposes of experiments ?—Surely. Where does the money come from ?

6534. But do you know of any case ?—I go upon the fact of their own prospectuses. As they do spend the money in that way, I suppose they do not spend it out of their private pockets.

6535. (*Mr. Erichsen.*) Are you aware that the funds of all medical schools connected with hospitals are totally distinct from the funds of those hospitals as charities ?—I am not aware of anything of that kind.

6536. Then before you made that statement do you not think that it would have been well to have made yourself acquainted with the source from which the funds that go to medical schools come ?—I made it from the statements of the hospitals themselves. As the money does not come, I presume, out of their private pockets, it is a fair inference that it comes out of the funds of the hospitals.

6537. Are you not aware that medical students pay fees ? If you look at these prospectuses you will see a schedule of fees that they have to pay for each class which they enter, and is it not reasonable to suppose that the funds for the purpose of experiments come out of those fees, and not out of the funds of the charity ?—I do not know that at all.

6538. (*Chairman.*) At any rate you have no information on that point ?—I will just refer to some notes given me by medical men, and perhaps I shall be able to give you something more definite. (*The witness referred to his notes.*) The statement is based, as I said, upon the prospectuses issued by the hospital authorities, at least I presume they are issued by them; you can buy them in shops.

6539. But you have no knowledge of any particular case in which experiments have been paid for from any funds which were contributed for the relief of the sick ?—You mean to ask whether I am aware of any money being handed over to buy a dog or a cat to be dissected alive, or not ?

6540. I mean whether you know of any single case which furnishes an example of that general statement which you have made—any single case in which the fact took place ?—The statement is based upon the prospectuses issued by themselves; those prospectuses show that they peform experiments upon living animals, and that seems to be held out as a source of attraction.

6541. But do you not perceive that there is a complete distinction between saying that experiments on living animals are performed, and saying that the expense of that proceeding is paid for out of the funds contributed for the hospitals ?—I do not think it matters very much where it comes from, as long as the thing is done.

Mr. *G. R. Jesse.*

20 Dec. 1875.

6542. But the statement is that the funds are misappropriated from the purpose for which they were contributed. Do you not think it makes a difference if it turns out that those funds are wholly applied to the purpose for which they were contributed?—Most decidedly I should think so.

6543. Then I ask, are you aware of any single case in which that has not been so?—I go upon their statement that they spend their funds (for they cannot do it without funds) in the torture of animals.

6544. (*Mr. Erichsen.*) I must press this question. You have made the gravest possible charge, not against the medical officers of hospitals, who have nothing to do with the distribution of the funds, but the gravest possible charge against the great body of treasurers and governing bodies of hospitals in this country that can possibly be made against any body of gentlemen, namely, that they have misappropriated funds entrusted to them for the cure and relief of the sick, to the performance of experiments upon animals; and I ask you to give me one single instance in Great Britain or Ireland by which you substantiate that charge against these gentlemen, who are not members of the medical profession, and who have no connexion with the medical profession?—You do not deny that those experiments are performed?

6545. I ask you, yes or no, or to give me an instance?—I say then, that my answer is based upon the prospectuses of those hospitals, where they say that living animals are experimented upon. The funds, therefore, must come out of the concern somehow.

6546. I would ask you further, whether it would not have been wise for you, before making that sweeping charge, to have made yourself acquainted with the fact that those prospectuses are issued by the medical schools in connexion with the hospitals, and that the funds of those schools are totally distinct from the funds of the charities? I would ask whether it would not have been wise for you to have ascertained that first of all?—I do not know. In this matter there is a great difficulty in arriving at information, and I might have tried a long time before I got any information on the subject. There is the simple fact that it is stated in these prospectuses of hospitals that experiments are performed on living animals; and we draw the very natural conclusion that the money for so doing is taken out of the funds of the hospital.

6547. Would it not have been quite sufficient to have written to the treasurer of any one hospital in connexion with which such a prospectus is issued, and to have asked him to afford you, for your society, information upon that subiect?—I do not suppose we should have received it. We have been very often baffled in trying to get information.

6548. Do you believe that the treasurers would mislead you?—I do not know; but I know that these practices are performed in secret. I am told that the doors are closed, and that strangers are not admitted; and therefore I do not think it probable that they would be communicative on the subject.

6549. I am not speaking with reference to the medical teachers in the schools. The charge which you have made does not affect a single medical man in the kingdom, but it affects the treasurers of hospitals in the country?—I have nothing further to say.

6550. You have also stated that the medical colleges and councils either sanction or advocate vivisection. Are you aware that the Council of the College of Surgeons in London expressly states in its regulations that vivisection is not required in physiological laboratories?—No, I am not. Is that so?

6551. Most decidedly?—I am very glad indeed to hear it. It is a sign, I hope, of better days.

The witness withdrew.

APPENDIX.

APPENDIX I.

LETTER addressed by command of Her Most Gracious Majesty the QUEEN to the President of the Royal Society for the Prevention of Cruelty to Animals, by Lieutenant-General Sir T. M. BIDDULPH, K.C.B.

MY DEAR LORD, Buckingham Palace, 10th June 1874.

THE Queen has commanded me to address you as President of the Society for the Prevention of Cruelty to Animals, on the occasion of the assemblage in this country of the foreign delegates connected with similar associations, and of the jubilee of the Society, to request you to give expression publicly of Her Majesty's warm interest in the success of the efforts which are being made here and abroad for the purpose of diminishing the cruelties practised on dumb animals. The Queen hears and reads with horror of the sufferings which the brute creation often undergo from the thoughtlessness of the ignorant, and she fears also sometimes from experiments in the pursuit of science. For the removal of the former, the Queen trusts much to the progress of education; and in regard to the pursuit of science, she hopes that the entire advantage of those anæsthetic discoveries from which man has derived so much benefit himself, in the alleviation of suffering, may be fully extended to the lower animals. Her Majesty rejoices that the Society awakens the interest of the young by the presentation of prizes for essays connected with the subject, and hears with gratification that her son and daughter-in-law show their interest and sympathy by presenting those prizes at your meeting. Her Majesty desires me to announce a donation of one hundred guineas towards the funds of the Society.

I am, &c.,
T. M. BIDDULPH.

The Earl of Harrowby, K.G.,
&c. &c.

App. II.

APPENDIX II.

§ 1. Correspondence with Sir George Duckett, Bart., of Weald Manor House, Bampton, Oxfordshire, whose name is at the head of the list of the Committee of the Society for the Abolition of Vivisection.

Vivisection Commission,
13, Delahay Street, S.W.,
11th December 1875.

Sir,

I am directed to request you will have the goodness to attend here on Wednesday next, the 15th instant, at 12 o'clock, to give evidence before this Commission.

I have, &c.,
Sir G. F. Duckett, Bart., &c. &c.
Nath. Baker, Sec.

Weald Manor House,
Bampton, Oxon,
12th December.

Sir,

I shall of course be ready to attend on the Vivisection Commission, but as my testimony is in no way connected with any personal experience, and that I can simply express my horror and repugnance that in a Christian country such monstrosities should be permitted, it might be desirable to state this to Lord Cardwell, especially as I can only attend at some personal inconvenience.

All that I could say would be, what the major part of the kingdom would say,—that the practice of vivisection, an abomination introduced from the continent, is horrid and monstrous, and goes hand in hand with Atheism.

Medical science has arrived probably at its extreme limits, and has little to learn, and nothing can be gained by *repetition* of experiments on living animals.

I am, &c.,
Nath. Baker, Esq., Sec., &c. &c.
George Duckett.

P.S.—If my attendance can be dispensed with as not material, perhaps you will let me hear by return of post.

Vivisection Commission,
13, Delahay Street,
13th December 1875.

Sir,

Your letter of the 12th instant was read at the meeting of the Commission to-day, and I was directed to inform you that they were most desirous that you should attend on Wednesnay next at 12 o'clock, and to assure you that they would not *unnecessarily* put you to the inconvenience of attending.

I am, &c.,
Sir George Duckett, Bart., &c. &c.
Nath. Baker, Sec.

Weald Manor,
Bampton, Oxford,
14th December 1875.

Sir,

Being under the impression that my attendance before the Commission is not compulsory, and having explained to you, for the information of that Commission, that I had no evidence to offer, I decline to attend.

If the Commission really wish for evidence of value, which can testify to the *hellish* practice of subjecting animals to torture, I beg to say that those I have named in the margin (*see below*) are the proper persons to afford it.

I am, &c.,
Nathaniel Baker, Esq., Sec., &c. &c.
George Duckett.

Geo. Hoggan, Esq., 13, Granville Place, Portman Square.
Edwd. Curtis May, F.R.C.S., Tottenham, Middlesex.
W. B. A. Scott, Esq., 16, Stonebridge Park, Willesden, N.W.
Mr. Abel, Surgeon, Gloucester.
Mr. Carter, Surgeon, Gloucester.
Mr. Lawrence, Hotel Keeper, Gloucester.

---

§ 2. Correspondence with Dr. Emanuel Klein, Assistant Professor at the Brown Institution, and Lecturer on general histology at St. Bartholomew's Hospital; and his amended proof as submitted to the Commission.

Vivisection Commission,
13, Delahay Street,
3rd November 1875.

Sir,

I beg to forward you a proof of your evidence for your correction.

I enclose a copy of a letter from Dr. Burdon Sanderson, which refers to your answers to one or two questions put to you, and shall be glad if you will inform me whether you wish to amend your answers.

I am, &c.,
Dr. E. Klein.
Nath. Baker, Sec.

49, Queen Anne Street, W.
November 1st, 1875.

My Lord,

I have been informed by a witness who appeared before the Commission last Thursday, Dr. E. Klein, that he (no doubt unintentionally) made a statement in relation to the investigations undertaken by me during the years 1873 and 1874 as to the pathology of certain infectious diseases for the Lords of Her Majesty's Council, to the effect that the living animals used in those investigations were purchased and maintained at the public expense.

It is important to me personally that this statement should be contradicted. The animals used were acquired by myself and maintained at my own expense throughout the investigation.

Dr. Klein was at this time employed by me as my assistant, and had no cognizance of my arrangements as to expenditure.

I have, &c.,
J. B. Sanderson.

The Brown Institution,
Wandsworth Road, S.W.
11th November.

Dear Sir,

May I take the liberty of asking you for another proof of my evidence, as I have unfortunately blotted my first proof so much that I cannot send it in to the printers in this condition.

Believe me, &c.,
N. Baker, Esq., Sec., &c. &c.
E. Klein.

Vivisection Commission,
13, Delahay Street,
12th November 1875.

Sir,

I beg to forward you another proof of your evidence, which I shall be glad to have back as soon as possible, for I am obliged to keep back the evidence of the 28th, and subsequent days, until I get your evidence.

I must also ask you to return the damaged proof at the same time, for I am answerable for all the copies I am supplied with.

I am, &c.,
Dr. E. Klein.
Nath. Baker, Sec.

The Brown Institution,
Wandsworth Road, S.W.,
16th November 1875.

Dear Sir,

I return you my evidence corrected. I may mention to you that when under vivâ voce examination, the fact of my being a foreigner made me often not able to appreciate all the purport of the questions, which were asked of me and that therefore my answers were not always such as I would have desired to give, if I had quite understood the questions. In revising the evidence I have endeavoured to remove the effect of any such misapprehensions.

I am, &c.
N. Baker, Esq., Sec., E. Klein.
&c. &c.

Vivisection Commission,
13, Delahay Street,
17th November 1875.

Sir,

I beg to acknowledge the receipt of your letter of the 16th instant, together with the proof of your evidence, and to reply that as your corrections appear to me to have exceeded the latitude usually allowed to witnesses, I must lay it before the Commission, and take their directions as to the course I am to pursue.

I am, &c.
Nath. Baker, Sec.

P.S.—I must ask you to return me the proof I originally sent you, which you damaged, for, as I told you when I sent you the duplicate, I am answerable for all the copies that are supplied to me.

Dr. E. Klein,
&c. &c.

Vivisection Commission,
13, Delahay Street,
19th November 1875.

Sir,

In my letter of the 12th instant, in which I forwarded you a second proof, I told you that I must have the original proof back.

On the 17th instant I again asked you to return it to me. I regret that I must now formally request you to return it to me at once.

I have, &c.
To Dr. E. Klein, Nath. Baker, Secretary.
&c. &c.

The Brown Institution,
Wandsworth Road, S.W.,
19th November.

Dear Sir,

I am very sorry to have given you so much annoyance as it appears from your letter. As I have stated on the occasion of my asking for a second proof of my evidence, the first proof has been accidentally damaged so much that it was quite useless. I therefore destroyed it and am not in a position, consequently, to comply with your request. I beg again to apologize if I should have put you to any inconvenience.

Believe me, &c.
N. Baker, Esq., Sec., E. Klein.
&c. &c.

Vivisection Commission,
13, Delahay Street,
11th December 1875.

Sir,

Your letter of the 16th November has been considered by the Commission, with the proposed alterations of your evidence. These appear to the Commission to be so much at variance with the letter and the spirit of the answers you gave at your examination, that the substitution cannot be permitted.

The Commissioners direct me to say that they observe with regret that after my letter of 12th November you should have destroyed the proof I originally sent you, and requested you to return.

If you desire it, the Commissioners will include in the Appendix your letter and the proposed alteration, with the correspondence which has passed with reference thereto.

I am, &c.
Dr. E. Klein, M.D.,
&c. &c. Secretary.

The Brown Institution,
Wandsworth Road, S.W.,
14th December 1875.

Sir,

I have received a letter which has no name subscribed to it, but which from its date and contents I presume to be written by you, informing me that the Vivisection Commission decline to receive on the ordinary footing the corrections which I made in the proof copy of my evidence, but are willing to include in the Appendix of their Report my letter and proposed alterations with the correspondence which has passed with reference thereto.

On this I must beg leave to repeat that the corrections or most of them, which I made in the proofs of my evidence, are necessary to express my real answers to the questions as I now (in reading) understand them; and that any publication of my evidence without those corrections will seriously misrepresent my meaning.

If therefore the Commission decline to accept my corrections as such, I must beg leave to withdraw the evidence as it now stands in proof.

Should the Commission, however, not permit me to withdraw it, I would respectfully request that they will allow this note to be included in their proposed publication as my protest against being held responsible for language, which does not convey my meaning and which I am told has already been much misunderstood.

With regard to the passage in your letter which expresses the regret of the Commission that after your letter of the 12th November I should have destroyed the proof you originally sent me, I beg to inform you, that that spoilt proof was destroyed before your letter of the 17th reached me. All my rough notes for the corrections had been written on it long before I received your letter of the 12th, and when I had afterwards transcribed these notes on to the second proof which you were so good as to send me, I regarded the first as merely waste paper and informed you accordingly.

Yours, &c.
N. Baker, Esq., Sec., E. Klein.
&c. &c.

Thursday, 28th October 1875.

Present:

The Right Hon. Viscount CARDWELL in the Chair.

The Right Hon. Lord Winmarleigh.
The Right Hon. W. E. Forster, M.P.
Sir J. B. Karslake, M.P.
John Eric Erichsen, Esq.
Richard Holt Hutton, Esq.
N. Baker, Esq., Secretary.

Mr. Emanuel Klein, M.D., called in and examined.

3528. (*Chairman.*) Are you Assistant Professor at the Laboratory of the Brown Institution?—Yes.

3529. Do you hold any other public appointment?—I am Lecturer on General Histology at the Medical School of St. Bartholomew's Hospital.

3530. Are you the author of the first section of this book, which is known as a handbook for the physiological laboratory?—Yes.

3531. Now are any of the experiments which you describe in that book experiments of a painful character?—Many of them are.

3532. Necessarily so?—Necessarily so.

3533. What was the intention in your view of the book as regards the practice of those experiments; are there any limitations to that practice?—It is a guide for students working in a laboratory under the supervision of some competent person who has to direct them how to perform it; that they should not perform it anyhow, but according to certain principles accepted in every laboratory.

3534. You have drawn in that book, I think, no distinction as to where anæsthetics are to be used, and where they are not?—No.

3535. Is that purposely on your part?—*It is distinctly understood that the experiments mentioned there are done under anæsthetics, except where it is expressly mentioned that they are not so.*

3536. But there is no general indication in that book, I think, that such is the case?—No, I do not think there is, nor is it necessary.

3537. Do you think there ought to have been?—Well, as I said before, it is to be a guide in a laboratory, not for private persons or amateurs; and there exist in every laboratory certain clear rules from which no one is allowed to deviate.

3538. What is your own practice with regard to the use of anæsthetics in experiments that are otherwise painful?—My own experiments do not involve very painful operations; and in them, except for teaching purposes, for demonstration, I never use anæsthetics, where it is not necessary to facilitate the proceedings. If I demonstrate, I use anæsthetics. If I do the experiments for my *pathological* research, except for convenience sake, as for instance on dogs and cats, I do not use them. On frogs and like animals I never use them.

3539. When you say that you only use them for convenience sake, do you mean that you have no regard at all to the sufferings of the animals?—No regard at all for such little suffering as is in my operations.

3540. You are prepared to establish that as a principle which you approve?—I think that with regard to an experimenter; a man who conducts special research and performs an experiment has no time, so to speak, for thinking what the animal feels or suffers. If anæsthetics ought to be used, he uses them. If not, he is like a man who performs a surgical operation in like circumstances. His only purpose is to perform the experiment, to learn as much from it as possible, and to do it as quickly as possible.

3541. Then for your own purposes you disregard entirely the question of the suffering of the animal in performing a painful experiment?—To the small extent which I have described, I do.

3542. Why do you regard it then when it is for a demonstration?—Because I know that there is a great deal of feeling against it in this country, and when it is unnecessary, one should not perhaps act against the opinion or the belief of certain individuals of the auditorium. One ought to take regard of the feelings and opinions of those persons before whom one does the experiment.

3543. Then am I wrong in attributing to you that you separate yourself entirely from the feeling which you observe to prevail in this country in regard to humanity to animals?—I separate myself as an investigator from myself as a teacher. I separate myself as an investigator, when I consult only my own feelings, from my position as a teacher, who has to consult and respect the feelings of others. I am as much opposed as anyone in this country to unnecessary or unprofitable cruelty to animals; but, for the purposes of scientific investigation, I hold that I have the same right to use the lower animals as has the sportsman and others in this country.

3544. But in regard to your proceedings as an investigator, you are prepared to acknowledge that you hold as entirely indifferent the sufferings of the animal which is subjected to your investigation?—During the time of the experiment and so far as indispensable for its purpose, yes.

3545. (*Lord Winmarleigh.*) Had you practised before coming to England?—Yes, in Vienna.

3546. Do you believe that that is a general practice on the Continent, to disregard altogether the feelings of the animals?—I believe that, there as here, in cases where it is necessary to inflict the pain, the experimenter (like an operating surgeon) would disregard the pain.

3547. Have you, since you have come to this country, had any proof of what you state now with regard to the different feeling that pervades the inhabitants of England with regard to the feelings of the animals on which you operate? Have you had any instances of the contrary feeling to that which you have just mentioned, on the part of Englishmen, since you have come to this country?—Yes, there is a great deal of difference.

3548. You have seen it exhibited?—Yes.

3549. Would you give the Commission an instance in which any such feeling has been exhibited?—I mean with regard to the journals; the agitation carried on in the different journals against what is called vivisection. There is no such thing abroad; there the general public takes no view, does not claim to pronounce any criticism or any judgment about scientific teaching and research in general. It assumes that men of science, like men in general, have conscience enough not needlessly to hurt brute animals.

3550. But with regard to the pupils before whom you lecture, have you ever seen any indication on their part of a disinclination to inflict unnecessary pain on animals?—If I do happen to perform a painful experiment where chloroform cannot be used, because it is against the purpose of the experiment, which is very rare, then I ask those before whom I do the experiment, whether they object to it.

3551. And what have you found?—If some of them object then I do not do it before them.

3552. Have they objected?—Very seldom. With the exception of one or two it has never happened that they have objected.

3553. But you believe that generally speaking there is a very different feeling in England?—Not amongst the physiologists; I do not think there is, but I cannot speak with authority.

3554. But amongst the people of England do you think there is a very different feeling from what exists upon the Continent on this subject?—Yes, I think so. In England they seem more disposed to take care of other people's consciences in matters they do not clearly understand.

3555. Seeing that there is that feeling, have you found that in yielding to that feeling in your lectures your experiments have not been so effective as they would have been if you had acted without anæsthetics?—Well, really I could not say. I have had no opportunity of judging.

3556. How long have you practised in England?—Four years and a half now.

3557. Always in London?—Always in London.

3558. You have never given lectures in the country?—No. I never perform experiments in my lectures; I only perform experiments for teaching purposes in my private class.

3559. To demonstrate?—To demonstrate and teach.

3560. Could you tell the Commission any particular experiment in which you think it is absolutely necessary to act in demonstration without anæsthetics?—Supposing, for instance, one intends to bleed a young dog to death by opening a vessel. With young dogs it is almost impossible to produce narcosis quickly, it takes always a considerable time; it is much sooner done by an assistant fixing the dog; at a single incision the carotid may be exposed, and the vessel may be opened in a few seconds, whereas with chloroform it would take a much longer time; the animal would howl, and would, I have no doubt, suffer a great deal more than when it was done without anæsthetics.

3561. Would the dog howl and exhibit pain while under anæsthetics?—While being chloroformed it would, and would suffer more pain and discomfort than if a single incision were made.

3562. Could you explain more in detail why you think it necessary, besides the point of time, to abstain from the use of anæsthetics in cases of research?—Let me again explain that my experiments do not involve severely painful operations, and I therefore am speaking of the (so to speak) superfluous use of anæsthetics. Where superfluous, they are to be objected to, because the whole attention of the investigator ought to be given to the purpose of the experiment. He has made clear to himself what he is going to do, how he is going to do it, and what he is going to learn by it. He generally chloroforms a dog when he experiments on a dog for convenience sake, in order not to be disturbed by the howling and the resistance; and so with cats. He does not do it with frogs. I do not think we have any right to regard the sensibility and feeling of a frog as being of a very high degree. And just as little as a sportsman or a cook goes inquiring while the sportsman is hunting or the cook putting a lobster into boiling water, just as little as one may expect these persons go inquiring into the detail of the feeling of the animal, just as little can the physiologist or the investigator be expected to devote time and thought to inquiring what this animal feels while he is doing the experiment. His whole attention is only directed to the making the experiment, how to do it quickly, and to learn the most from it that he can.

3563. But do you think that where it is only a question of time a professor of physiology is not bound to consult humanitarian feelings?—Certainly; but I must again draw a distinction between an investigator and a professor of physiology. I understand a professor of physiology to be a man who teaches, and there I think it is quite right that when one performs an experiment before a class one should use anæsthetics, but an investigator has no occasion to use anæsthetics except from the real necessity of the case and where severely painful operations are in question.

3564. Is that really the only reason that you can give for not using anæsthetics?—It is to a great extent; it is the chief reason I should say; there is no place for considering that point.

3565. (*Mr. Forster.*) You mentioned, I think, that there were certain rules in laboratories; what are those rules?—That no one is allowed to make an experiment except a professor or the assistant professor is present and tells him how to do it, and makes him acquainted with the purpose of the experiment, doing it perhaps the first time before the student is going to repeat it.

3566. Do those rules in the English laboratories say anything about anæsthetics?—Well, generally it is understood, where it is not against the purpose of the experiment, that they are used; it is a thing understood by itself.

3567. Is that a written rule?—There is no written rule that I know of any kind.

3568. Have you found much progress in physiological science lately in this country?—I think so very considerable.

3569. You find more attention given to it than when you first came?—Yes, considerably more.

3570. And several students, I suppose, that attend your lectures take great interest in it?—Yes.

3571. Do you think that many of them are carrying on private investigations?—No; I do not believe that any private person carries on investigations except in a laboratory.

3572. Do they come to your laboratory and try experiments?—Yes; those who carry on special investigations come to the laboratory of the Brown Institution, and do it under me or Dr. Sanderson.

3573. What is your connexion with the Brown Institution?—As I said, I am assistant professor in the laboratory, but I have nothing to do with it as a hospital for animals. I have only the use of the laboratory, which is part of the Brown Institution. My official position connects me with the work which is done for Mr. Simon.

3574. Your laboratory is in the rooms connected with the Brown Institution?—Yes, on the same ground.

3575. How do you get the animals that are practised upon in the Brown Institution?—I buy them.

3576. And do you buy them with funds that come out of the Brown Institution?—No; those used for pathological researches are not bought by the Brown Institution. The researches that I am conducting myself are for the medical officer of the Privy Council.

3577. (*Chairman.*) By what medical officer?—Of the Privy Council, Mr. Simon. The experiments have been very few in the last few years for special research, but those that have been made have been always in connexion with scientific investigation into the causes of disease carried out for Mr. Simon.

3578. (*Mr. Forster.*) And have the animals upon which you have been experimenting in your researches and investigations been furnished by Mr. Simon?—No. Those for teaching purposes are bought quite privately.

3579. I want to know with regard to your own private investigations, are the animals that are obtained for that purpose, and upon which you try experiments, obtained with the assistance of Mr. Simon's grant out of the Privy Council?—I do not do any private experiments on higher animals except for pathological researches for Mr. Simon. The animals for these investigations were provided by Dr. Sanderson, as whose assistant I was acting.

3580. Have you done any other?—No.

3581. What are the experiments in pathological researches?—For instance, producing artifical tuberculosis, or trying to communicate typhoid fever to the lower animals, experiments on small-pox in sheep, and on pyemia.

3582. You spoke about your own personal experience in what may be strictly called vivisection; that, I suppose, is not so much in this country as abroad?—No, not to such an extent.

3583. Can you at all recollect what was the vivisectional experiment in this country with which you had to do which caused the greatest pain without anæsthetics?—I should think applying lunar caustic to the cornea of a frog; it is mentioned at page 38 of the handbook.

3584. Would you be good enough to tell me the time that that experiment would last from the period at which you would first be obliged to give pain to the frog?—It greatly depends upon what kind of frog it is. If it is a large vigorous frog, for instance, a large frog from the Continent, it takes a much shorter time than with a small frog.

3585. This is not the frog which you get here, I suppose?—We get them from Holland.

3586. (*Chairman.*) You import them for the purpose?—Yes.

3587. (*Mr. Forster.*) Take one of those frogs, then, and tell me how long the experiment would last?—At present I do not practise it so long as the passage in the book would imply; I do not allow it to stay an hour after the cauterisation. When doing it on living frogs the animals are allowed to live say 10 or 20 minutes after cauterisation, the cauterisation itself takes little time.

3588. And what becomes of the frog after that time?—It is killed.

3589. (*Lord Winmarleigh.*) Always?—Generally killed; I may say always killed.

3590. (*Mr. Forster.*) Have you performed any experiments in England upon dogs or cats; upon dogs, for instance?—Yes, I have.

3591. What sort of experiments?—Pathological experiments; I have injected pyemic fluids into the veins of dogs to produce pyemia, or septicæmia. So with cats. Then I have used dogs for producing tuberculosis, and I have used dogs and cats for producing typhoid fever.

3592. Have you cut up any dogs or cats by vivisection?—If I inject into the vein, I must cut much as might be done in bleeding a patient from the arm; you cannot do it without cutting.

3593. Those are what you call pathological experiments?—Yes, for pathological purposes.

3594. I am now speaking of the other kind of experiments on living animals, which would be more strictly perhaps called vivisection; have you done them to dogs or cats in England?—No.

3595. But have you for private investigation?—As I mentioned just now for pathological experiments on pyemia, typhoid fever, septicæmia, and tuberculosis; not for physiological purpose.

3596. Have you, for private investigation, tried any experiments on dogs or cats, not pathological, but physiological experiments?—No, not directly for physiological experiments. I may have used a dog which has been used at the same time for pathological purposes, also for physiological.

3597. (*Chairman.*) When you use a dog for physiological purposes, do you adopt any particular mode of fastening that dog?—No, it is fastened on a large board, the four limbs are fastened.

3598. And how are they fastened?—With broad bands as when giving chloroform.

3599. (*Mr. Forster.*) You were stating that you considered it was so important to be absorbed upon the object of the experiment, that you could think of nothing else, and therefore could not really, in your opinion, afford time to consider the feelings of the animal; do you not sometimes find an inconvenient interruption from the cries of the animal?—I do then use chloroform, that is what I said; I use anæsthetics for convenience sake in the sense already spoken of.

3600. Do you ever use curare for that purpose, to stop the cries?—Curare involves other difficulties, the animal ceases to breathe becauses it paralyses the movement for breathing, and that might be against the object of the experiment. The animal, for instance, is to be kept alive for some time after the experiment is over; that could not be done after artificial respiration has been induced.

3601. But practically, has not the howling of the dogs interfered with experiments?—Dogs do howl also when you chloroform them.

3602. Do you try experiments with any animals that do not signify pain so loudly?—Rabbits.

3603. They do not howl, I suppose?—They do not.

3604. Then of course the same motive would not induce you to use chloroform in their case?—No.

3605. In fact, I suppose with rabbits you would not use chloroform?—I prefer and use choral hydrate; but, as a general rule, for my not severely painful scientific investigations, I do not use chloroform, or any other anæsthetic, except for convenience sake, in dogs and cats, and for no other animals as a general rule. There may be exceptions perhaps, but as a general rule, I think I am safe in saying I do not use it. I wish distinctly that it be understood that I refer only to such experiments as I myself make, namely, injection into the abdominal cavity and injection into the vein.

3606. You gave it as your opinion, that your views on the subject, although not shared by the British public generally, were the views of the British physiologists?—I would not say that distinctly, but I know a few of them, and I think that is the view held by them, but of course being a foreigner I have no authority of saying so.

3607. What is your precise connexion with the Government department of the medical branch of the Privy Council?—I have been engaged carrying out pathological investigations for Mr. Simon.

3608. That is to say, that Mr. Simon asks you to give him your assistance in a particular matter; there is no arrangement with you by which you may be considered an officer of the Privy Council, is there?—I do not think there is.

3609. (*Chairman.*) But the animals that are used for these purposes are paid for by the public money?—I do not know; they are provided by Dr. Sanderson. I must mention that I make extremely few pathological inquiries. I have not made any other experiments on living animals except those for artificial tuberculosis, for small-pox, and for typhoid fever. I understood that I was asked about my opinion, and I gave it, but it is another question whether I actually do make severe experiments. If I were to be called upon to perform experiments of this kind, I would perform them.

3610. (*Mr. Forster.*) I understand you to say, that as regards physiological experiments, you have not tried physiological experiments to any extent in England?—Very few indeed, and chiefly only on frogs.

3611. Have you done so at all in connexion with your employment by Mr. Simon?—No, none whatever.

3612. But what experiments you have tried have been tried in the Brown Institution at your own cost, I suppose?—In my private room. Those that I do for teaching purposes, physiological purposes just referred to, I do in my private room; I live there.

3613. Can you at all give us any idea of the number of animals that you find it necessary to obtain for experiments for medical investigations connected with the Privy Council?—At my work I do not think there have been more than 14 or 15 animals used in the last two years.

3614. (*Lord Winmarleigh.*) What were they?—There were three monkeys; of course, I would not call that vivisection; it was simply feeding them on typhoid material, and this has nothing to do with vivisection. I will leave out these therefore. Then there were three dogs and two cats, and a few mice, four white mice, I think, and several sheep for small-pox investigation.

3615. (*Chairman.*) Now in regard to the Brown Institution, what is your precise relation to the Brown Institution, do you receive any remuneration from it?—None whatsoever.

3616. You live in the building?—Yes.

3617. And this private room of which you speak is a private room belonging to the Brown Institution?—It belongs to the laboratory of the Brown Institution.

3618. That is to say, it is a part of the property held in trust by the London University?—I believe so.

3619. And you reside in it?—Yes.

3620. What is your particular duty to the London University?—I am ashamed to say I do not know; it has never been made clear to me what my position is there except that a title has been given to me, that of assistant professor to Dr. Sanderson, and that I am working in the laboratory, conducting pathological researches; those gentlemen who come there to undertake special pathological researches work under my direction.

3621. And are those pathological researches for the benefit of the Brown Institution?—I do not know that it has ever been put down in that way. Of course, investigations which would illustrate the nature of the diseases of animals would promote one of the objects for which the institution was founded.

3622. The pathological researches are made upon animals?—Yes.

3623. Are those animals furnished to you by the Brown Institution?—No; I make *pathological* experiments only for the medical officer of the Privy Council.

3624. Then for the London University you make no pathological experiments?—None.

3625. Then no animals are furnished to you by the London University?—None.

3626. Are these pupils of yours in any way connected with the London University?—No; they are pupils from different hospitals who wish to enter more closely into the study of microscopical anatomy.

3627. And in the teaching of those pupils you draw no distinction between painful experiments and non-painful experiments if the students themselves raise no objection to see the animal subjected to pain?—Yes; I think that would be quite what I expressed before.

3628. Therefore any students who come there, so far as your teaching and influence are concerned, adopt, I presume, the principle that you have adopted?—Yes.

3629. And consider that a physiological inquirer has too much to do to think about the sufferings of the animals?—Yes, except beforehand; may I be allowed to state, with regard to experiments for teaching purposes, that there are extremely few that I really make. I wish again to repeat that my investigations are almost entirely of a histological and pathological character, that is into the study of healthy and diseased structures.

3630. But I presume that the experiments which you perform for original research are, many of them, of a painful nature?—I have performed experiments which eventually produce pain with reference to artificial tuberculosis, because I regard it as painful to produce a disease coming on very slowly in an animal by injecting into its abdominal cavity a foreign material; but I do not regard it as a painful experiment to produce typhoid fever in an animal, seeing that the material has no effect whatsoever.

3631. But now coming to vivisection proper, you do perform in this laboratory operations which involved a great deal of pain to the animal?—Not as operations, but in their eventual results we do occasionally; of course they are very few, they are as follows: injection into the abdominal cavity and into the vein.

3632. And without any question of employing anæsthetics, unless it happens to be for your own convenience to do so?—Yes, anæsthetics would not be applicable, but the animal is generally not allowed to continue long in the diseased state.

3633. And that principle, so far as your influence goes, is derived from you by the pupils who come to benefit by your teaching?—That may be so or not, that applies only to the experiments which are for teaching purposes.

3634. (*Mr. Forster.*) With regard to the pathological experiments which you tried in connexion with Mr. Simon, you mentioned that there was one that is particularly painful, the one connected with tuberculosis?—Yes, pyemia, in its results but not in the operation itself.

3635. And that is done by injecting?—Yes, by injecting a certain fluid into the abdominal cavity, or into a vein.

3636. I suppose the operation of the injection is painful?—No, the injection itself is nothing, the results which follows thereafter may be painful.

3637. Is there no operation which is painful?—I daresay injecting into the vein of a dog is a painful operation, the making of a cut into the skin, but that is all. About as painful as bleeding.

3638. How long would that last?—Not half a minute.

3639. You give no chloroform, I suppose, when that is done?—No, it is quite unnecessary.

3640. Are there any other of these experiments which require what may be called operations in doing them?—No, only injecting into veins and injecting into the abdominal cavities. I would not regard that as a painful operation any more than a subcutaneous injection into a man for the relief of pain. Besides those I do not remember any.

3641. When you take hold of an animal for this purpose, what is done with it; do you bind it up while you are making this injection?—If it is a large vigorous animal, as a dog, we do bind it. A cat we generally must chloroform.

3642. Why do you not chloroform a dog?—I chloroform a cat because I am afraid of being scratched.

3643. Why not a dog?—If it is a small dog there is no fear of being bitten by the dog.

3644. I hardly need ask you, with your earnestness in investigation, you would run the risk of a scratch if you thought that giving chloroform would spoil the experiment?—Yes; if I had to open an artery to insert a cannula into it (I am talking only of conditions which may be; I do not say it has happened with me), I should chloroform the animal, in order not to be scratched, or the cannula to be torn out.

3645. Have you had any directions from Mr. Simon with regard to pathological investigations in consequence of any minute which I wrote when I was in the Privy Council?—Yes, I remember.

3646. Do you remember what they were?—Yes, I think I remember that it was your express desire to use animals for pathological experiments as little as possible, and to produce as little pain as possible; those were the contents.

3647. Do you recollect anything definite in those instructions, or in Mr. Simon's instructions to you upon those instructions, with regard to the use of chloroform?—The fact is that I do not remember that we used any animal strictly for vivisection, except injecting into the vein and injecting into the abdominal cavity; for one could not call it vivisection injecting lymph of small-pox into the skin of a sheep, any more than one could injecting vaccine lymph into the arm of a child.

3648. Have you ever had instructions from Mr. Simon, that with regard to experiments, pathological or physiological, conducted by you, chloroform was to be used in the case of any severely painful operation?—I had no direct relations with Mr. Simon, and besides we had no severely painful operations.

3649. Would you inform him beforehand of what you were going to do in the way of vivisection?—No, there were no vivisections, as the word is used, to be performed, and I think Mr. Simon knows too much himself about scientific investigation to interfere with an investigator.

3650. I want to know whether he has ever told you, as a general rule, for your guidance, that in any severely painful operation chloroform is to be administered for any experiment connected with the Privy Council?—The only direction which Mr. Simon gives is general. He asks us to do this or that investigation; but to say how we are to do it, or to criticise the results we obtain, I do not think he ever undertakes, and besides I have had no direct relations with Mr. Simon.

3651. (*Lord Winmarleigh.*) He never gives directions under those circumstances, whether it should be done under anæsthetics or not; is that what you mean?—There is no occasion for him to give them.

3652. (*Sir J. B. Karslake.*) Have you given us now the most painful experiments that you have ever performed by

Ir. Simon's instructions ?—I have given you a list com- rising injection of pyæmic matter or tuberculous matter ito the abdominal cavities of animals, or into the jugular ein, injecting lymph in the skin of sheep, and feeding nimals on typhoid dejecta.

3653. Then it has not fallen to your lot at present to erform what you would call a more severe experiment vith the knife than that of opening the jugular vein of an nimal ?—No other.

3654. Now is there any pain caused to a dog in the dministration of chloroform ?—I think there is; at least e see a great deal of struggling going on in the animal; ie animal struggles very hard.

3655. Before it takes effect you mean ?—Before it takes ffect.

3656. In each of those cases which you have mentioned me in which you performed the experiments by the irection of Mr. Simon, was it necessary to keep the animal live after the actual incision or actual injection ?—Yes, lways.

3657. For how long a time ?—Sometimes for weeks, ometimes for days.

3658. Then after the original injection or incision, the ain would be caused by the development of the disease ?— ooner or later, yes.

3659. In those cases, I suppose, chloroform would be seless ?—Quite so, it would not be used.

3660. As I understand you, if you were directed to per- orm an operation for the purpose of ascertaining some act, or supposed fact, with reference to the nerves of a og, and it became necessary to cut the back of the dog everely for the purpose of exposing the dog's nerves, for ie sake of saving yourself inconvenience, you would at nce perform that without the use of anæsthetics ?—Yes, if were against the purpose of the experiment.

3661. And it is only because the dog might howl, or get ito contortions, that you would use anæsthetics at all ?— es, that is to say, this would be one reason for use, where therwise the anæsthetics might be unnecessary.

3662. But it so happens that for Mr. Simon's purposes, t all events, you have never been called upon to perform uch an experiment ?—Never.

3663. Do I understand you to say, that you have any ublic class, in contradistinction to the private class you ave spoken of, of individuals who attend the laboratory ?— o public class.

3664. Then the experiments you perform involving pain animals are in the presence of certain gentlemen who ome to the laboratory for the purpose of learning ?—Yes, nd altogether there are only three or four such experi- ients.

3665. How long have you been performing those ex- eriments before a private class ?—I may say three years.

3666. Can you tell me in the course of each year how iany experiments you have performed before that class ivolving pain to animals ?—Two.

3667. Two in each year ?—Yes; sometimes two, and ometimes three.

3668. Will you give us the three which you have per- ormed ?—The cauterisation of the cornea of a frog; then ie injection into the blood vessels of a frog; then the auterisation of the cornea of a kitten, but this is done nder hydrate of chloral.

3669. That is an anæsthetic ?—Yes.

3670. And was that done in that way to satisfy the upils, or for your own convenience; I am now upon the xperiments for teaching purposes ?—That was also done or keeping the animal quiet while doing it, and for the upils convenience, and for mine.

3671. Have you ever enunciated to these private pupils vho come before you your view that a physiologist en- aged in the research should pay no attention to the pain f animals, but should avoid the use of anæsthetics ?—That, s you state it, is not my position, but I have never had ccasion to speak to pupils of private research, of special esearch.

3672. As I understand you, the case has occurred in your rivate laboratory ?—Not remonstrance exactly. I remem- er it only once; I said, "I am going to perform this or hat experiment."

3673. Just tell us what it was ?—The application of austic to the cornea of a frog. I said, "Do you object to hat," and only on one occasion I remember one said, Yes, I think it is useless."

3674. How many pupils were present at that time ?—I ave never more than five or six at a time.

3675. Did you continue to perform the experiment not- vithstanding that remonstrance ?—No, I did not do it; I lo not generally do these experiments for all the pupils at nce; because my pupils are not as in a class carried hrough instruction in the same subject, but every one works in a special subject; and so I do the experiment for one.

3676. But as I understand, the whole number of experiments before every pupil in the class, or every individual, does not exceed three ?—I mean three kinds; but the experiment may repeat itself several times.

3677. How many animals are sacrificed, do you suppose, in the course of the year for the purpose of these experiments for teaching your private pupils ?—I can say only in a rough estimate. I should not think more than 10 or 12.

3678. And of those, what is the proportion that would be of the lower animals—frogs for instance ?—Frogs form the greatest number; one kitten, perhaps, among the whole lot.

3679. You say one kitten; have you only destroyed ono kitten in these experiments ?—No; I have only made one experiment on a kitten. I have cut off the heads of many kittens, but have made an experiment on a living kitten for teaching purposes only once.

3680. Have you ever made an experiment on a living dog for teaching purposes ?—No; I think not.

3681. In the case of frogs, you never take out any part of the brain before you perform these experiments, do you ? —No.

3682. That is a short process, is it not ?—Yes.

3683. But you think it unnecessary, because you say that a physiologist has a right to do as he likes with the animal ?—Yes.

3684. Now in your own private research, what animals have you chiefly used since you have been in England ?— Guinea-pigs, rabbits, rats, mice, frogs, dogs, cats, monkeys, and sheep.

3685. But in the case of monkeys, as I understand, that was only for the purpose of ascertaining the effect that food would produce upon them ?—Yes, feeding them with typhoid material.

3686. Can you give me what, in your judgment, was the most painful experiment that in your private research you have tried since you have been in England, the one causing the most pain to the animal; I refer to the actual pain inflicted in the course of cutting the animal ?—I do not think I have done any more severe experiment than cutting the skin, and injecting into the jugular vein.

3687. That is the most painful experiment you have performed in England, you think ?—That is the most painful operation I have performed in England in my special research.

3688. I think you have said that you have been engaged in this Brown Institute a little more than four years ?— Yes.

3689. Did you come direct from Germany ?—Yes, from Vienna.

3690. Have you studied in Germany ?—Yes, in Vienna.

3691. What laboratory did you come from ?—Professor Stricker's, in Vienna.

3692. How many years had you studied under him ?— I have studied only pathology and histology under him for about four years.

3693. How many lectures of his did you attend in the course of the year ?—No lectures.

3694. Or how many demonstrations ?—His laboratory was a laboratory where special researches were carried out, and I being his private assistant was more or less connected with all the experiments that were carried out there, either directly or indirectly.

3695. And might I ask you, in the course of the last year that you were engaged as assistant to Dr. Stricker, about how many experiments were performed in his laboratory ?—I could not say.

3696. Was the number in hundreds ?—No, far less.

3697. What animals did he chiefly use ?—Rabbits and dogs.

3698. Not frogs ?—Yes, frogs also.

3699. However the largest animals he used were dogs and rabbits ?—Yes.

3700. Now there was one answer which you gave in the course of the questions put to you in which you said that other physiologists in England take the same view of the subject that you do. Do you know any physiologist that works in his private laboratory except yourself in England ? —I think that is more a matter of private talk.

3701. You have given an answer; I want to know whether you have any accurate information which enables you to say that other physiologists in England take the same view of the subject that you do ?—I have no accurate knowledge about it. I only expressed an opinion, a belief. I believe it is so; I could not prove it, and I do not know for certain whether it is so; I believe that there are other physiologists who take the same view that I do.

3702. (*Mr. Erichsen.*) You make a distinction, I suppose, between physiologists and practical physicians?—Yes.

3703. Of late years there has been a great change, has there not, in that respect in the scientific world in England. Formerly experiments were usually made by practising physicians and surgeons in order to determine some special point in practice?—Yes.

3704. For instance, a man ligatured an artery in order to see what the effect was?—Yes.

3705. But of late years a class has grown up in the medical profession, biologists and physiologists, who do not practice medicine in any way whatever, who may or may not have been educated for the medical profession, but who devote the whole of their time to the study of the laws of life upon animals?—Yes, and whose results are afterwards turned to account by the practitioners.

3706. And it was to them that your remarks were applicable?—Yes.

3707. (*Mr. Hutton.*) Did I rightly understand you to say that the frogs were always killed after this cornea operation, or only sometimes?—As a general rule they are killed.

3708. You have to excise the cornea, have you not?—Yes.

3709. And if they are not killed what is done with them? At that time they are general killed—at least to my knowledge always—but there may be one or two occasions where I have not had time myself to see whether my orders are carried out or not.

3710. (*Chairman.*) Do you mean when you say "killed" that the operation killed them?—Before the cornea is cut out the animal is generally decapitated, and then the cornea is cut out.

3711. (*Mr. Hutton.*) Whether that is always so done you are not sure?—I cannot speak with certainty about any one thing, but as far as my knowledge goes it is so.

3712. I take it that the operation of scraping the cornea which precedes, I believe, the cauterising it, would be a very painful one to the human being?—Yes; but caustic is ordinarily applied to the human eye without anæsthetics.

3713. You suppose that a frog does not suffer as a man in that operation?—Yes, I think it does not.

3714. But you say it would be a painful one; and the frog is killed at the end of an hour, or what period?—I would say 20 minutes.

3715. Is that the English or German frog?—The German frog.

3716. And how long would the English frog be kept alive?—Twice as long.

3717. Have you ever performed in England this operation described in your part of this handbook, at page 108, on the mesentery of a frog?—I have done it.

3718. It would be a much more painful one, would it not?—That is done always under curare.

3719. But it is quite an open question whether curare s, or is not, an anæsthetic for a frog?—I think it is; Schiff made some experiments to prove that it is.

3720. Claude Bernard thinks it is not, I believe?—Those that believe in experiments will, I think, agree that it is.

3721. But supposing it is not an anæsthetic, this experiment on the mesentery would be much more painful, would it not, than the cornea experiment?—Well, there is another question necessarily involved in this, namely, how much less would a frog feel if he does not breathe?—The fact is, that the frog does not breathe with his lungs after the application of curare, but breathes only through the large vein of the skin.

3722. And you think that might diminish the suffering?—I have no doubt it does.

3723. Have you performed this experiment on the mesentery of a frog before your private class, or not?—I have done it perhaps twice, not before a class, but before persons who were there for teaching purposes. I have done it several times for the purpose of pathological investigation.

3724. You have done it always under curare?—Yes; it could not be done without it.

3725. You have to keep the creature still, you mean?—Yes.

3726. And that is the reason for your using it?—Yes; and even if curare were not an anæsthetic (which I think it is) I believe that the frog would undoubtedly feel much less when the breathing is reduced to that very small amount which takes place through the vein of the skin.

3727. And have you ever done this experiment at page 98, about the injection of small mammalian animals during life?—I never did that before pupils.

3728. Have you done it in this country for private research?—I have never done it myself in England; I have done it in Vienna.

3729. Have you ever had to make experiments on arterial pressure in England, in the course of your teaching?—No.

3730. Can you give me the least idea of about the quantity of animals required for the Vienna laboratory in a year?—No.

3731. Not even an approximate number?—No.

3732. It is a very large laboratory?—Yes. Professor Stricker's laboratory is; the room is small, but the amount of work done there is very great, or it was so.

3733. And of course a considerable number of animals are used there?—Yes, very considerable.

3734. Is it at all as large as Ludwig's laboratory at Leipsic?—No.

3735. Have you ever studied there?—No.

3736. You could not give any idea what the consumption of animals there is?—Not in the least.

3737. Are there any other foreign laboratories that you have studied in?—No. I have studied only in Professor Brücke's and Professor Stricker's, in Vienna.

3738. And Professor Stricker's is the larger of the two?—Yes.

3739. And you think that the view of scientific men on the Continent is your view, that animal suffering is so entirely unimportant compared with scientific research that it should not be taken into account at all?—Yes, in cases where important results to mankind are in question, and the results cannot be got without animal suffering.

3740. Have you told us everything that is done in the Brown Institute; have you had no inquiries there but what you have mentioned in answer to Sir John Karslake?—I believe I have not omitted anything.

3741. With regard to any experiments on dogs which you have made, have they been simply cutting the carotid artery or the jugular vein?—Yes, I think that is all.

3742. There is nothing that has lasted then for any considerable time?—No; I could not remember now anything else.

3743. I thought I understood you once to say that you had performed on dogs operations that had lasted half an hour?—Half a minute, perhaps, but not half an hour.

3744. I thought you said operations that might take half an hour, but that they were never done before pupils?—I do not remember anything of the kind except bleeding a puppy to death by opening the carotid, and that is a matter of half a minute.

3745. (*Sir John Karslake.*) What was that for?—To draw out as much blood as possible, say for injection of the lymphatics of the lung. That can be done most conveniently, and with best success, by first bleeding the animal to death.

3746. (*Mr. Forster.*) Do you recollect whether Mr. Simon informed you that when I was in office I had said something to him about this, or did he give you a minute that I wrote?—I think he spoke to me about it; but really it is so long ago that I could not be certain.

3747. You cannot recollect whether he gave you a minute?—No; my business relations with him at that time were exclusively through Dr. Sanderson.

3748. You do not recollect his giving you any words written by me, to this effect, "That no experiments on "living animals should be conducted at the cost of the "State without the employment of some anæsthetic in "case of painful operation, and without a report from time "to time by the gentleman conducting the experiments, "explaining their object and showing their necessity for "the purpose of discovery." Do you recollect seeing those words?—No. May I be allowed to repeat that at that time I was not connected directly with Mr. Simon. I was at that time simply an assistant of Dr. Burdon Sanderson, so that Mr. Simon could not have had occasion to give me that instruction in an official way.

3749. When you were put directly under him you had not that minute laid before you, as I understand you?—I am only quite recently in direct business relation with Mr. Simon, and this is not in experimental investigation.

3750. (*Mr. Hutton.*) Have you ever discussed this question of the relation of animal pain to physiological inquiry with Dr. Sanderson?—I think we did.

3751. And I think that he differs from you on that point?—Yes; he does differ from me.

3752. But he understands your views on the subject?—I do not think we have entered very minutely into it; but I remember I had repeatedly occasion to say, "I do not "think it is a matter of necessity in our experiments to "administer chloroform in a general way."

3753. (*Lord Winmarleigh.*) You stated just now that you believed that curare was an anæsthetic for certain animals?—Yes.

3754. What are your reasons for that belief?—My reasons are chiefly the experiments given by Schiff; he made some experiment, and I think it proves that curare does under certain conditions act on the sensitive nerves. We know that it paralyses the mortor nerves.

3755. But Claude Bernard says, does he not, that it does not destroy the sensitiveness?—That was the general belief until the experiments of Schiff's were known.

3755. Have you read Claude Bernard's reasons for his view?—No, I have not.

3757. (*Mr. Hutton.*) You are perhaps aware that Claude Bernard describes two experiments on man with curare?—No.

3758. (*Lord Winmarleigh.*) Will you state, as shortly as you can, the exact reason for supposing that curare is an anæsthetic?—First of all, the reason which I gave to Mr. Hutton, namely, that if you poison a frog with curare you stop the breathing through the lungs; the animal breathes only through the cutanean veins; and it is quite clear that it does not keep up its vitality, its sensitiveness, to such an extent by the small amount of oxygen it may get through the vein.

3759. Would that destroy sensitiveness?—It would lower it.

3760. But not destroy it?—I do not think it would absolutely destroy it, but it would lower it undoubtedly. And secondly, I believe, with Schiff, that curare does act as an anæsthetic for this reason: if you ligature, for instance, the artery of the lower limb of a frog and then poison the animal with curare, you will find that the movement of that limb is not destroyed, because curare could not penetrate into the muscles of that region of which the artery has been ligatured. If now you pinch the leg which is *not* curarised the frog will show movement with the same limb, because its muscles are not paralysed. But if then you pinch that limb where the curare is acting on the muscles, the animal does *not* exhibit any movement with the uncurarised limb. That shows that where the muscles have been paralysed also the sensitive nerves have been paralysed.

3761. Is that movement indicative of pain?—Yes; we take it cæteris paribus, that when we pinch the frog and it does not move it does not feel.

3762. Dr. Schiff practises in Florence, does he not?—Yes.

3763. Is he a large experimentor in physiology?—Yes; from the written publications of his researches, I may say perhaps, that he is one of the largest.

3764. Are you aware whether he uses anæsthetics?—I am not. I could not say.

The witness withdrew.

App. III.

APPENDIX III.

§ 1. Vivisection. By Sir Thomas Watson, Bart., one of the Physicians in Ordinary to the Queen, and formerly President of the Royal College of Physicians.

Vivisection—the cutting into live animals for scientific purposes—is it defensible? If so, for what special purposes may it be practised, and under what conditions and limitations?

If it be true—as it certainly is true—that at a small expense of suffering in one of the lower animals, we may obtain knowledge which enables us to prevent or mitigate pain much more severe and lasting—or even to 'ward off peril to life, or to prolong life—in a human being, surely vivisection is more than justifiable. For the teacher, who must first be a learner, it may become, within assignable restrictions and conditions, nothing less than a positive duty.

What are those restrictions?

1. I hold that no vivisections are excusable which are made at random, simply to see what will happen. To justify them at all there must be some definite object in view of a previously instructed mind, some plain question to settle, some important doubt or uncertainty to remove, some hypothesis containing the promise of service to humanity to be confirmed or confuted, at least some reasonable hope and prospect of resulting benefit.

2. I hold that no man is justified in making any painful experiment upon a living creature who does not possess the skill, judgment, intelligence, and previous knowledge requisite to render the experiment successful and instructive; that all possible care should be taken by the experimenter to prevent the frustration of his object through want of foresight, of needful preparation of the necessary apparatus and implements; through a bungling use of these: or through the ignorance or stupidity of assistants; and to guard against everything that might prolong or enhance the pain which may be inseparable from the experiment, or that might defeat its conclusiveness, and so waste the painful trial altogether.

3. I hold that no teacher, or man of science, who by his own previous experiments or by his absolute knowledge of trustworthy and conclusive experiments made by others, has thoroughly satisfied himself of the solution of any physiological problem—is justified in repeating the experiments, however mercifully they may be conducted, or even in taking away the animal's life, merely to appease the natural curiosity of a class of students, or of scientific friends and acquaintances; still less for the sake of display or self-glorification.

4. If the alleged inferences from former experiments are not generally accepted by competent judges as just, or thoroughly established, then a single repetition of the experiments, to settle once for all a disputed point of importance, may reasonably be allowed.

It is probable that the general public are not fully aware of the methods whereby the pain incidental to vivisection may be abated or prevented.

There are two ways in which this most desirable end may be attained.

First, by pursuing the proposed inquiry immediately after the sudden decapitation of the animal. The pain of such decapitation is certainly very brief in duration, and presumably very slight in degree.

Some explanation becomes necessary here.

We feel, in common with all animals, by means of our nervous system. Our nervous system consists of the brain, with its prolongation or appendage the spinal cord, from which last nerves proceed and are distributed in branches innumerable to every part of the surface of the body, as well as to its internal organs. It is a demonstrable fact that the faculty of sensation resides (so to speak) in that part of the nervous system which lies within the skull. The trunk of a headless animal can feel nothing. The mere organic life that may remain within it for awhile, is perfectly analogous to the life of a vegetable; and the movements which may be evoked by mechanical or chemical irritation are as entirely without sensation of any kind, as are the movements of a sensitive plant when its leaves are handled. I hold this to be absolutely certain, although it may be difficult for any one to believe me who looks upon the animal movements, some of which appear to indicate deliberate intention or choice. But we have clear evidence in proof of my assertion, in what occasionally happens in the living human body. Disease, or injury, sometimes furnishes us with that sort of opportunity for observing, which, when we contrive to obtain it upon one of the lower animals, we call an experiment. Disease, or accident, sometimes shuts off from a part of the body the sentient faculty, by severing the spinal cord at a point where its severance is not fatal to life. What happens? The parts supplied with nerves from the severed portion of the cord are completely paralysed. The subject of this condition loses all sensation and sensibility, and all power of voluntary motion in his lower limbs. He feels in them no touch, no prick, or cut; you may burn them with a red hot iron, but he is not conscious of the burning. He cannot move a muscle belonging to the palsied limbs by the strongest effort of his will. Yet let the soles of his feet be tickled, even with a feather, and his legs and thighs start up in vigorous convulsive movements; movements which he cannot prevent or control if he wishes to do so, and of which, indeed, he himself is not even aware, unless he happens to see them.

Facts of this kind, to the reality of which I can bear personal testimony, convince us that similar movements in an animal recently beheaded—even movements which seem, but only seem, to be directed by conscious choice and purpose—are really as independent of all bodily suffering or sensation as are the motions of a mechanical automaton, contrived and constructed by human ingenuity. We view these phenomena with a deep sense of admiring wonder; wonder at the exquisite skill (if that word may with reverence be used), the incomparable skill and power manifested by the Creator, in so ordaining the fashion and endowments of the animal frame.

To proceedings such as I have now described, in which sentient life is suddenly extinguished by removing the animal's head, unjustifiable cruelty can hardly be imputed. If we are warranted in putting the lower animals to death in order to nourish and sustain the human body—and even the Brahmin cannot help doing this—we surely are warranted in taking similar means in order to learn how to cure or prevent its diseases.

It may perhaps be objected that, apart from the rapid beheading, there is in such cases no vivisection at all. The subject of the experiments is virtually dead. The animal life is gone; the slowly ebbing organic vitality alone subsists to furnish for a time, by its peculiar properties and reactions, the information of which the operator is in quest.

But—leaving this quibble—*secondly*, a temporary suspension of sensibility to pain, similar and equal to that which is absolute and final after decapitation, may be effected by the use of what are well known under the title of anæsthetic agents. And if, as is often the case, the knowledge sought for can thus be gained without destruction of life, and with little or no subsequent pain or detriment to the animal, surely this also is a proceeding exempt from blame, and not to be denounced.

There may be, there doubtless are, instances in which the manifestation of actual pain by the subject of the experiment, is the very thing necessary to test and solve the physiological question at issue. In these cases, which I believe are not very numerous, the restrictions and limitations of which I have spoken require to be most strictly observed and enforced.

If the experiment be such as to entail permanent harm, or even abiding discomfort to the animal after its sensibility is restored by the passing off of the anæsthetic influence —then it will be the most merciful, and therefore the right proceeding, to prolong that influence till the whole life, organic as well as animal (or sentient), is extinct.

Much more might be said on the whole question, but I shall have done enough if I have been enabled to calm disquietude upon the subject of vivisection, by showing that, however fearfully it may often have been abused, it may be both lawfully and mercifully practised; and that, when so practised, it is not open to the charge of wanton cruelty; but on the contrary, is deserving of our approval and gratitude. It cannot be reckoned a pleasurable exercise; and it ought never to be resorted to for the satisaction of mere curiosity, but solely for the immediate or the ultimate benefit of society, which not unnaturally is inclined to look upon it with horror and disgust.

The consolatory thought remains, that in proportion as our knowledge of the functions of the nervous system approaches to completeness, will the need for these painful methods of "interrogating nature" continually lessen, and finally cease.

---

§ 2. Royal College of Surgeons of England; Extract from the Regulations respecting the Education and Examination of Candidates for the Diploma of Member of this College.

Section II.

Professional Education.

III. Candidates will be required to produce the following Certificates, viz.:—

1. Of being twenty-one years of age.
2. Of having been engaged, subsequently to the date of passing the preliminary examination, during four years, or during a period extending over not less than four Winter and four Summer Sessions, in the acquirement of professional knowledge.
3. Of having attended lectures on anatomy, during two Winter Sessions.
4. Of having performed dissections during not less than two Winter Sessions.
5. Of having attended lectures on general anatomy and physiology during one Winter Session.
6. Of having attended a practical course of general anatomy and physiology during another Winter or a Summer Session, consisting of not less than thirty meetings of the class.

Note A.—By the practical course referred to in Clause 6, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, &c.; but it is not hereby intended that the learners shall perform vivisections.

&c., &c., &c., &c.

---

§ 3. Documentary Evidence furnished by Mr. John Anthony, M.D., of Washwood Heath, near Birmingham, and referred to in his evidence.

Extracts from the Article "Innervation" in "Bowman's Physiology," published by Parker 1845, as descriptive of experiments performed by injuring or removing portions of the brain on living animals.

Spinal Cord.—Flourens found by experiment,—

If in an animal which breathes without a diaphragm, as in a bird, the spinal cord be gradually removed in successive portions, proceeding from below, the movements of respiration go on, and deglutition is performed. The higher senses are unimpaired. (Flourens.)

Medulla Oblongata.—Irritation in any part of the medulla oblongata excites convulsive movements in muscular parts which receive nerves from it.

Spasms of the glottis, difficulty of deglutition result from irritation of the medulla oblongata.

Restiform bodies.—Flourens injured the restiform bodies, and his experiments in that direction were of no value.

Cerebral Hemispheres.—When the cerebral hemispheres have been removed, as in Flourens' and Magendie's experiments, the bird can stand, walk, or fly.

Medulla Oblongata.—Experiments of Le Gallois and Flourens showed that the destruction of a portion of the medulla oblongata impairs or destroys the respiratory actions.

Corpora Striata.—(Experiments by Longet and Lafargue.) The animals remain immoveable after the removal of the corpora striata and only move after application of some external stimulus. Removal of the corpus striatum of one side caused weakness of the opposite side.

Optic Thalami.—The results of experiments add little to our knowledge of the functions of the optic thalami, the taking off successive slices or any cutting or pricking did not occasion muscular agitation, or induce contraction of the pupils.

Longet found the removal of the optic thalami in the rabbit was followed by paralysis in the opposite side of the body, but this experiment was done after the removal of the hemisphere, and the corpus striatum, and Longet also says that in his experiments on the optic thalami the paralysis was produced equally of the anterior and posterior extremities.

Destruction of Tubercula Quadrigemina.—Flourens found that the destruction of either of the tubercula quadrigemina was followed by loss of sight on the opposite side, and that the removal of both deprived the animal altogether of vision but did not affect the locomotion, or its intellectual power, or its sensibility,—except to light. So long as any portion of the roots of the optic nerves remained uninjured the iris continued to respond to the stimulus of light.

If the lobes of the brain and cerebellum were removed leaving the tubercles untouched the iricles would continue to contract.

When the injuries inflicted on the tubercula quadrigemina were deep, more or less general convulsive movements were produced. If one tubercle were injured, the opposite side only was so affected. The convulsions were due to the lesion of the central parts of the medulla oblongata.

Longet saw the same movements in pigeons in which he had *evacuated the humours of one eye.*

* *Cerebellum.*—The facility with which the cerebellum may be removed or injured, especially in birds, without involving the other segments of the brain, renders it a much more favorable object for direct experiment. A skilful operator may remove the greater part of the whole of the cerebellum without inflicting any injury on the hemispheres or other parts. Flourens removed the cerebellum from pigeons "*slice by slice.*" During the removal of the superficial layers there appeared only a slight feebleness; on reaching the middle layers, an almost universal agitation was manifested * * the animal performed rapid and ill-regulated movements, it could hear and see. After the removal of the deepest layer the animal had lost completely the power of standing, walking, leaping, or flying. The power had been injured by the previous mutilation, but now it was completely gone. When placed upon his back he was unable to rise * * he evinced an incessant restlessness * * he could see the instrument raised to threaten him with a blow, and would make a thousand contortions to avoid it but did not escape. Volition and sensation remained but that of co-ordinating these movements with combined actions was lost.

Animals deprived of the cerebellum are in a condition very similar to that of a drunken man * * * The fruitless attempts which they make to stand or walk is sufficient proof that a certain degree of intelligence remains.

Cerebellum.—After the *well known experiments of Magendie* of dividing the crus cerebelli, the animal was seen to roll over on its long axis towards the side on which the injury was inflicted.

M. Longet says, "Take two pigeons, from the one completely remove the cerebral lobes, and from the other only half the cerebellum; the next day the first will be seen firm upon his feet; the second will exhibit the unsteady and uncertain gait of drunkenness."

Corpus Callosum.—Direct experiments by Longet on the commissure of the corpus callosum yielded only negative results.

Bowman in the course of his Article on the Nervous System gives the following remarks:—"Vivisections upon "so complex an organ as the brain are ill-calculated to lead "to useful or satisfactory results; but we do not hesitate "to quote such as have been made."

[The foregoing descriptions embrace only a small portion of the experiments I saw made a matter of public exhibition at the College de France in Paris some few years prior to the publication of Bowman's standard work on physiology. I do not so much quarrel with the experiments themselves, made by the hands of such able men as Flourens, Magendie, and Longet, as I do with the series of sensational exhibitions made of them before a mixed audience in a large lecturing theatre.]

J. Anthony, M.D., Cantab.

Washwood Heath, near Birmingham.
October 31, 1875.

---

* I saw a number of creatures subjected to this experiment.

App. III.

§ 4. Extract from "Archives de Physiology," volume II. of 1869, page 650. Translation read by George Hoggan, M.B. Minutes of Evidence, q. 4111.

Observations faites sur un chien curaré, par Paul Bert.

Sous le peau d'un chien vigoureux de moyenne taille, j'introduis 6 centigrammes de curaré à l'état solide et 6 centigrammes de la même substance dissous dans 6 grammes d'eau. Après quelques minutes, l'animal trébuche sur les pattes de devant marchant sur les ongles, puis il tombe et présente tous les symptômes habituels de cet empoisonnement; il défèque, urine un peu, émet beaucoup de salive visqueuse, et pleure abondamment.

J'ouvre la trachée et j'y introduis la buse d'un soufflet mis en mouvement intermittent par une chute d'eau agissant sous une roue à auges (appareil installé par M. Gréhant dans le laboratoire de M. Claude Bernard, au College de France). J'exécute ainsi une respiration artificielle très regulière.

Le nerf pneumogastrique du côté droit est mis a découvert et lié; on en fait autant pour le nerf sciatique du même côté.

Après quelques minutes, le nerf sciatique n'agit plus sur les muscles. Pendant dix heures on examine, d'heure en heure, l'action des nerfs, l'état des pupilles, &c.; et à chaque observation, on constate les faits suivants, qu'il suffira de décrire une fois.

La pupille du côté droit est contractée, celle du côté gauche très dilatée. La galvanization du pneumogastro-sympathique au cou, d'un côté ou de l'autre, améne la dilatation pupillaire et la projection de l'œil en avant; cet effet est naturellement plus marqué à droite, mais il est réel à gauche.

La galvanisation du nerf pneumogastrique d'un côté ou de l'autre arrête parfaitement le cœur.

L'iris du côté sain (côté gauche) se contracte quand on fait tomber sur lui la lumière.

Enfin, et c'est là le point sur lequel je désire appeler particulièrement l'attention, l'excitation galvanique du bout central du nerf sciatique lié, celle du nerf médian, celle du nerf sous orbitaire, amène une contraction vésicale qui, le sphincter urethral étant paralysé, se traduit par le rejet d'une petite quantité d'urine. Cet effet ne s'obtient que par l'intervention des nerfs de sensibilité appartenant à la vie animale. Ni le pneumogastrique, ni le sympathique au cou, ni les nerfs splanchniques ne donnent rien de semblable.

Après dix heures de respiration artificielle, l'animal était refroidi de 3 ou 4 degrés (température de l'air 12°).

Le lendemain matin il etait mort, et l'appareil à respiration artificielle marchait toujours; mais peut-être, pendant la nuit, y avait-il eu quelque irregularité.

L'urine contenue dans la vessie, joint à celle qu'on avait antérieurement recuillie, contenait beaucoup de sucre; la salive visqueuse, sécrétée en grande abondance, a donné avec le réactif bleu une précipité jaune peu considerable, mais manifeste. C'est la première fois, je crois, que l'on trouve du sucre dans la salive à la suite des diabétes artificiels.

Mais revenons à l'action des nerfs de sensibilité sur les contractions vesicales.

Ce fait est interressant en lui-même parcequ'il explique certaines relations connues entre la vessie et des nerfs sensitifs, tel que l'envie d'uriner consécutive à la sensation vive du froid extérieur, à l'entrée dans un bain froid ou très chaud, &c. De plus, il sera possible, en poursuivant son étude, de résoudre certaines questions très interressantes pour la physiologie. D'une part, l'origine intramédullaire, et le lieu de sortie des nerfs moteurs de la vessie pourront être par là facilement déterminés. On verra, ensuite, quelle voie suivent ces ébranlements centripètes venus, par exemple, du nerf sous-orbitaire, pour parcourir ainsi toute la longueur de la moelle épinière, s'ils s'empruntent exclusivement des cordons blancs, ou s'ils se répandent dans la substance grise. Les expériences de Budge et de M. Schiff pourront être ainsi utilement complétées.

Quoi qu'il en soit, voici un chien empoisonné par le curaré et chez qui, pendant dix heures, les actions du nerf pneumogastrique et des nerfs du grand sympathique ont persisté, soit qu'on excitât ces nerfs directement par l'électricite, soit qu'on les mit en jeu par l'intervention de leur excitant naturel, c'est à dire par voie réflexe.

---

§ 5. Proposed Statute for the Limitation of Vivisection. Prepared and handed in by the Royal Society for the Prevention of Cruelty to Animals.

Whereas it is expedient to restrict the practice of vivisection and the performance of other experimental operations upon animals, and to prohibit the instruction of students, in classes and otherwise, by such means; Be it enacted:

1. The term "vivisection" in this Act shall include every experiment producing or of a nature to produce pain or disease in any animal, as well as the cutting or wounding of any living animal otherwise than for the purpose of curing or alleviating some disease with which such animal is affected, or of killing it; the term "anæsthetic" in this Act shall be taken to mean any agent which will produce complete insensibility to pain.

2. It shall not be lawful, after the first day of January one thousand eight hundred and seventy-six, to perform a vivisection save in a place which is registered in pursuance of this Act.

Notice of any place in which it is intended to perform vivisections shall be given in Great Britain to one of Her Majesty's Principal Secretaries of State (in this Act referred to as the Secretary of State), and in Ireland to the Chief Secretary to the Lord Lieutenant of Ireland (in this Act referred to as the Chief Secretary); such notice shall be signed by a member of some college of physicians or surgeons, and shall sufficiently describe the place in respect of which it is given; and the Secretary of State or Chief Secretary may cause any place with respect to which such notice has been given, to be entered on a register to be kept for the purposes of this Act in such form and under the management of such persons as the Secretary of State and Chief Secretary may respectively direct.

Subject to the consent of the Secretary of State and Chief Secretary respectively as aforesaid, an entry on the register in pursuance of this section may continue in force for twelve months from the date thereof and no longer; but such entry may be at any time renewed on a fresh notice being given as required by this section.

Any person who, after the first day of January one thousand eight hundred and seventy-six, performs a vivisection in a place which is not registered in conformity with this section, shall be deemed to have committed an offence against this Act.

3. From and after the passing of this Act no person shall perform, or cause to be performed, or take part in performing, except as herein-after provided, any vivisection without having previously obtained a license as herein-after is provided.

4. That it shall be lawful for Her Majesty's Principal Secretary of State and for the Chief Secretary for Ireland as aforesaid, immediately on the passing of this Act, or so soon thereafter as may be required, to grant a license to practise vivisection to any fellow or member of any college of physicians or surgeons, or to any graduate or licentiate of medicine, or to any person lawfully qualified to practice medicine in any part of the United Kingdom, or to any professor or teacher of anatomy, medicine, surgery, physiology, on application from such person for such purpose in the form set forth in the Schedule to this Act, accompanied by a certificate in the form set forth in the same Schedule, and signed by one at least of the following persons; viz., the President of the Royal Society, the Presidents of the Royal Colleges of Surgeons in London, Edinburgh, or Dublin, the Presidents of the Colleges of Physicians in London, Edinburgh, or Dublin, and also by a professor of physiology, medicine, or anatomy in some University in Great Britain, or recognized by the Colleges of Surgeons and Physicians aforesaid.

5. And whereas under and in pursuance of an Act passed in the second and third years of the reign of King William the Fourth, intituled "An Act for regulating schools of anatomy," certain inspectors of places where anatomy is carried on, are appointed for certain districts in Great Britain and Ireland, be it enacted that, immediately upon the registration of a place, or the granting of a license for the practice of vivisection, the said Principal Secretary of State or Chief Secretary as aforesaid respectively, shall give notice of such registration or license having been granted to the inspector so appointed for the district in which the applicant for such registration or license shall reside.

6. Every such license may at any time be revoked by such Secretary of State and Chief Secretary respectively.

7. No person shall perform, or cause to be performed, or take part in performing any vivisection while lecturing to,

or giving instruction to students in classes or otherwise, or for the illustration of lectures in schools, hospitals, or colleges, or in any other places.

8. No person shall perform or take part in performing any vivisection for the purpose of attaining manual skill.

9. No person shall perform, or cause to be performed, or take part in performing any vivisection upon any animal without having first subjected such animal to the influence of an anæsthetic so as to render it wholly insensible to pain.

10. No person who shall perform, or cause to be performed, or take part in performing any vivisection upon an animal so subjected as aforesaid, shall omit to destroy such animal before the effect of the anæsthetic ceases.

11. A license under this Act shall extend to any person assisting the holder of the license, provided the person assisting acts in the presence and under the direction of such holder.

12. A justice of the peace, on information on oath that there is reasonable ground to believe that vivisections are performed at any place not registered, or by any person not licensed in pursuance of this Act, may issue his warrant, authorising any officer of police to enter and search such place where it is alleged that such vivisections are being carried on, and to take the names and addresses of the persons found therein.

Any person who refuses admission on demand to a police officer so authorised, or who obstructs such officer in the execution of his duty under this section, or who refuses on demand to disclose his name and address, or who gives a false name or address, shall be liable to a penalty not exceeding five pounds, or to a term of imprisonment not exceeding two months.

13. A book or books shall be kept by every inspector of places where anatomy is carried on of all licenses granted by Her Majesty's Principal Secretary of State, or by the Chief Secretary as herein-before mentioned, together with the names, surnames, descriptions, and addresses of the persons to whom such registrations or licenses have been granted, together with the date of the granting or revocation of all such registrations or licenses, and such book or books shall be open at all reasonable times to inspection by any person on payment of two shillings.

14. Every person who shall be so licensed as herein-before is provided shall keep a book at the place registered as herein-before provided, in which he shall enter in plain words and figures, and with consecutive numbers, the particulars of each and every vivisection which he shall perform or take part in performing, the object and result of such vivisection, the kind of animal upon which such vivisection is performed, the kind of anæsthetic used, and the period of time which elapsed between the time at which the anæsthetic first took effect and the destruction of the animal, together with the name, surname, description, and address of the person from whom such animal was received. Such book shall be in the form set forth in the Schedule to this Act annexed, and such book, and the place registered as herein-before provided shall at all times be open to the inspection of such inspector of anatomy so appointed as aforesaid, or of Her Majesty's Principal Secretary of State or such Chief Secretary as aforesaid, or of such person as they respectively may appoint for the purpose.

15. Any person offending against any of the provisions of this Act shall forfeit and pay a penalty not exceeding ten pounds for the first offence, or imprisonment for a term not exceeding three months, and a penalty not exceeding fifty pounds for the second and every subsequent offence, or imprisonment for a term not exceeding six months, upon summary conviction before a justice of the peace.

16. The Act passed in the eleventh and twelfth years of the reign of Her Majesty, intituled "An Act to facilitate "the performance of the duties of justices of the peace out "of sessions, within England and Wales, with respect to "summary conviction and orders," shall be read with and as if it were part of this Act.

[Then follow the usual sections relating to jurisdiction in Ireland and Scotland, and to appeals, schedule, &c., &c.]

---

§ 6. A Bill intituled An Act for regulating the Practice of Vivisection. (Presented by the Lord Hartismere ; ordered to be printed 4th May 1875.)

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. This Act may be cited as the Vivisection Act, 1875.

2. It shall not be lawful, after the first day of January one thousand eight hundred and seventy-six, to perform a vivisection save in a place which is registered in pursuance of this Act.

Notice of any place in which it is intended to perform vivisections shall be given in Great Britain to one of Her Majesty's Principal Secretaries of State (in this Act referred to as the Secretary of State), and in Ireland to the Chief Secretary to the Lord Lieutenant of Ireland (in this Act referred to as the Chief Secretary); such notice shall be signed by a member of some college of physicians or surgeons, and shall sufficiently describe the place in respect of which it is given; and the Secretary of State or Chief Secretary shall cause any place with respect to which such notice has been given, to be entered on a register to be kept for the purposes of this Act in such form and under the management of such persons as the Secretary of State and Chief Secretary may respectively direct.

An entry on the register in pursuance of this section shall continue in force for twelve months from the date thereof and no longer; but such entry may be at any time renewed on a fresh notice being given as required by this section.

Any person who, after the first day of January one thousand eight hundred and seventy-six, performs a vivisection in a place which is not registered in conformity with this section, shall be deemed to have committed an offence against this Act.

3. Any inspector of anatomy may at any time visit and inspect any place which is for the time being registered in pursuance of this Act.

4. A vivisection shall not (save as herein-after mentioned), after the first day of January one thousand eight hundred and seventy-six, be performed on any animal until such animal has been placed completely under the influence of an anæsthetic; and for the purposes of this section the substance called urari or curare shall not be deemed to be an anæsthetic.

Any person may apply to the Secretary of State or Chief Secretary for a special license to perform vivisections without the use of anæsthetics, and the Secretary of State or Chief Secretary may, as he thinks fit, grant or refuse such license.

There shall be paid in respect of every such license the sum of ten pounds, and every such license shall continue in force for six months, and no longer.

Any person who performs a vivisection in contravention of this section shall be deemed to have committed an offence against this Act.

5. The Secretary of State or Chief Secretary may remove any registered place from the register on its being proved to his satisfaction that any provision of this Act has been contravened in such place.

6. A justice of the peace, on information on oath that there is reasonable ground to believe that vivisections are performed at any place not registered in pursuance of this Act, may issue his warrant authorising any officer of police to enter and search such place, and to take the names and addresses of the persons found therein.

Any person who refuses admission on demand to a police officer so authorised, or who obstructs such officer in the execution of his duty under this section, or who refuses on demand to disclose his name and address, or who gives a false name or address, shall be liable to a penalty not exceeding five pounds.

7. Any person who commits any offence against this Act for which no other penalty is imposed shall be liable to a penalty not exceeding twenty pounds.

All offences and penalties under this Act may be prosecuted and recovered in manner directed by the Summary Jurisdiction Acts before a court of summary jurisdiction.

The term "Summary Jurisdiction Acts" means as follows:

As to England, the Act of the session of the eleventh and twelfth years of the reign of Her present Majesty, chapter forty-three, intituled "An Act to facilitate the "performance of the duties of justices of the peace out "of sessions within England and Wales with respect "to summary convictions and orders," and any Acts amending the same:

As to Scotland, "The Summary Procedure Act, 1864:"

As to Ireland, within the police district of Dublin metropolis, the Acts regulating the powers and duties of justices of the peace for such district, or of the police of such district; and elsewhere in Ireland, "The Petty Sessions (Ireland) Act, 1851," and any Act amending the same:

The term "court of summary jurisdiction" means in England and Ireland any two justices of the peace or any metropolitan stipendiary or other magistrate empowered by law to do alone or with others any act authorised to be done by more than one justice of the peace; and in Scotland any justice or justices of the peace, sheriff, or other magistrate by whatever name called, proceedings before whom for the trial or prosecution of any offence or for the recovery of any penalty under any Act of Parliament, the provisions of the Summary Jurisdiction Act, 1864, may be applied:

In Scotland the following provisions shall have effect;

(1.) All jurisdiction, powers, and authorities necessary for the court of summary jurisdiction under this Act are hereby conferred on that court:

(2.) Every person found liable under this Act in any penalty shall be liable in default of immediate payment to imprisonment for a term not exceeding three months, and the conviction and warrant may be in the form of No. 3 of Schedule K. of the Summary Procedure Act, 1864.

8. In this Act, the term "vivisection" means the cutting or wounding, or treating with galvanism or other appliances, any living vertebrate animal for purposes of physiological research or demonstration, also the artificial production in any living vertebrate animal of painful disease for purposes of physiological research or demonstration.

---

§ 7. A Bill to prevent Abuse in Experiments on Animals made for the purpose of Scientific Discovery. (Prepared and brought in by Mr. Lyon Playfair, Mr. Spencer Walpole, and Mr. Evelyn Ashley; ordered to be printed 12th May 1875.)

Whereas it is expedient to prevent cruelty and abuse in the experiments made on living animals for the purpose of promoting discoveries in the sciences of medicine, surgery, anatomy, and physiology:

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. Save as herein-after mentioned, no person shall, for any purpose whatever, make an experiment causing pain, or of a nature to cause pain, on any live animal.

Any person acting in contravention of this section shall be guilty of a misdemeanor, or shall be liable, on prosecution before a court of summary jurisdiction, to a penalty not exceeding *fifty pounds*, or imprisonment for a term not exceeding *three months*.

2. Any person, for the purpose of new scientific discovery, but for no other purpose, shall be permitted to make an experiment on a live animal of a nature to cause pain notwithstanding this Act and the Prevention of Cruelty to Animals Act (passed in the twelfth and thirteenth years of Her present Majesty, chapter ninety-two), provided that the following conditions are complied with:

(1.) That the animal shall first have been made insensible by the administration of anæsthetics or otherwise, and shall continue to be insensible during the whole of such experiment; and

(2.) That, if the nature of the experiment be such as to seriously injure the animal, so as to cause to it after-suffering, the animal shall be killed immediately on the termination of the experiment.

3. Nothing in this or in the Prevention of Cruelty to Animals Act contained shall be taken to prohibit any person holding a license, as herein-after provided under this Act, from subjecting any live animal to an experiment without the use of anæsthetics, provided that in making such experiment the following conditions are all complied with:—

(1.) That the experiment is made for the purpose of new scientific discovery, and for no other purpose; and

(2.) That insensibility cannot be produced without necessarily frustrating the object of the experiment; and that the animal should not be subjected to any pain which is not necessary for the purpose of the experiment; and

(3.) That the experiment be brought to an end as soon as practicable; and

(4.) That if the nature of the experiment be such as to seriously injure the animal, so as to cause to it after-suffering, the animal shall be killed immediately on the termination of the experiment:

(5.) That a register of all experiments made without the use of anæsthetics shall be duly kept, and be returned in such form and at such times as one of Her Majesty's Principal Secretaries of State may direct.

4. Any person desirous to obtain a license under this Act may apply for the same to one of Her Majesty's Principal Secretaries of State. Such application shall be in the form set forth in the Schedule to this Act, and shall be signed by the applicant, and shall be accompanied by a certificate in form set forth in the same Schedule, and signed by one at least of the following persons; viz., the President of the Royal Society, the Presidents of the Royal Colleges of Surgeons in London, Edinburgh, or Dublin, the Presidents of the Colleges of Physicians in London, Edinburgh, or Dublin, and also by a professor of physiology, medicine, or anatomy in some university in Great Britain, or recognised by the Colleges of Surgeons and Physicians aforesaid.

Provided that if the applicant be a professor or lecturer of or in physiology, medicine, anatomy, or surgery in any university in Great Britain, or in any college incorporated by Royal charter, or a professor or lecturer in any one of such sciences employed by Government, such a certificate shall not be required; but, instead thereof, his application shall be countersigned by the registrar, president, principal, or secretary of such university or college.

5. Upon receiving such application the Secretary of State may, if he think fit, grant to the applicant a license under this Act.

6. A license under this Act shall, unless earlier revoked, be in force, in the case of the holder being a professor or lecturer as herein-before mentioned, during such time as he shall continue to hold such professorship or lectureship, and in any other case for the term of five years. Provided that from time to time, when a license expires a Secretary of State shall renew the same upon receiving a written application from the holder, without requiring a fresh certificate or any countersigning of the application.

7. A Secretary of State may at any time, on cause shown, revoke any license granted under this Act.

8. A license under this Act shall extend to any person assisting the holder of the license, provided the person assisting acts in the presence and under the directions of such holder.

9. All offences and penalties under this Act may be prosecuted and recovered in manner directed by the Summary Jurisdiction Acts before a court of summary jurisdiction.

The term "Summary Jurisdiction Acts" means as follows:

As to England, the Act of the session of the eleventh and twelfth years of the reign of Her present Majesty, chapter forty-three, intituled "An Act to facilitate the "performance of the duties of justices of the peace "out of sessions within England and Wales with "respect to summary convictions and orders," and any Acts amending the same:

As to Scotland, "The Summary Procedure Act, 1864:"

As to Ireland, within the police district of Dublin metropolis, the Acts regulating the powers and duties of justices of the peace for such district, or of the police of such district; and elsewhere in Ireland, "The Petty Sessions (Ireland) Act, 1851," and any Act amending the same:

The term "court of summary jurisdiction" means in England and Ireland any two justices of the peace or any metropolitan stipendiary or other magistrate empowered by law to do alone or with others any act authorised to be done by more than one justice of the peace; and in Scotland any justice or justices of the peace, sheriff, or other magistrate by whatever name called, proceedings before whom for the trial or prosecution of any offence or for the recovery of any penalty under any Act of Parliament the provisions of the Summary Jurisdiction Act, 1864, may be applied:

In Scotland the following provisions shall have effect:

(1.) All jurisdiction, powers, and authorities necessary for the court of summary jurisdiction under this Act are hereby conferred on that court:

(2.) Every person found liable under this Act in any penalty shall be liable in default of immediate payment to imprisonment for a term not exceeding three months, and the conviction and warrant may be in the form of No. 3 of Schedule K. of the Summary Procedure Act, 1864.

10. Any person who has been convicted of any offence punishable by this Act by any justices may appeal in England to the next general or quarter sessions of the peace which shall be held for the city, county, town, or place wherein such conviction shall have been made, in Scotland to the sheriff of the county, after the expiration of ten days from the day when such conviction shall take place, provided that such person enter into a recognizance within three days next after such conviction, with two sufficient sureties, conditioned to try such appeal, and to be forthcoming to abide the judgment and determination of the court at such general or quarter sessions, or of the sheriff, and to pay such costs as shall be by such court or sheriff awarded; and the justices or sheriff before whom such conviction shall be had are hereby empowered and required to take such recognizance; and the court at such general or quarter sessions and sheriff respectively are hereby required to hear and finally determine the matter of such appeal, and may award such costs to the party appealing or appealed against as they or he shall think proper.

In Ireland any person who has been convicted of any offence punishable by this Act may appeal to the next court of quarter sessions to be held in the same division of the county where the conviction shall be made by any justice or justices in any petty sessions district, or to the recorder at his next sessions where the conviction shall be made by the divisional justices in the police district of Dublin metropolis, or to the recorder of any corporate or borough town when the conviction shall be made by any justice or justices in such corporate or borough town (unless when any such sessions shall commence within ten days from the date of any such conviction, in which case, if the appellant sees fit, the appeal may be made to the next succeeding sessions to be held for such division or town), and it shall be lawful for such court of quarter sessions or recorder (as the case may be) to decide such appeal, if made in such form and manner and with such notices as are required by the said Petty Sessions Acts respectively herein-before mentioned as to appeals against orders made by justices at petty sessions, and all the provisions of the said Petty Sessions Acts respectively as to making appeals and as to executing the orders made on appeal, or the original orders where the appeals shall not be duly prosecuted, shall also apply to any appeal made under this Act.

Schedule.

Form of Application.

I, *M.N.*, of [*description and occupation, with particulars of any scientific, academical, or other like qualification*], do hereby declare that I am engaged in the study of the science of physiology, and especially in the making of researches, with the view of advancing physiological knowledge, and that I desire to obtain a license under the provisions of "The Experiments on Animals Act, 1875," empowering me to make experiments on living animals; and I hereby undertake that in making any experiments under such license, if granted, I will conform to the conditions and restrictions contained in sections 2 and 3 of the said Act.

Dated 187 . (Signed) *M.N.*

[*These sections to be printed on the back of the application.*]

Form of Certificate.

We, *A.B.*, President of the Royal Society, and *C.D.*, hereby certify, for the information of the Secretary of State for the Home Department, under the provisions of the Experiments on Animals Act, 1875, that the above-named *M.N.* is engaged in prosecuting such researches as are described in the above application, and that he is, in our opinion, a person properly qualified to carry on such investigations, and to have granted to him the license for which he applies.

(Signed)

Names.	Descriptions.
A.B.	
C.D.	

Dated this day of , 187 .

Form of License.

I, Her Majesty's Secretary of State for the Home Department, having received from *M.N.* residing at [*description and occupation*] an application, under the provisions of the Experiments on Animals Act, 1875, accompanied by certificate, such as is required by the same Act, of which certificate and application copies are appended hereto, do hereby, in exercise of the authority given to me by the said Act, license the said *M.N.* to make experiments on living animals, in the manner and subject to the conditions and restrictions set forth in the said Act, during the period of five years from the date hereof, [*or, in the case of a professor or lecturer, under section* , "*for so long as he may retain and fulfil the duties of his*" *office as such professor or lecturer aforesaid.*"]

Dated this day of 187 .

§ 8. Digest of Replies to Questions forwarded to the principal Medical Schools and Veterinary Colleges in Great Britain and Ireland.

Name of Medical School, &c.	1. Are any experiments performed on live animals (including frogs) for scientific or teaching purposes at —— or in the Hospitals, Schools, and Laboratories connected with it?	2. State as accurately as you can the number of such experiments performed in the course of the year.	3. State for what purposes such experiments are made, whether for original research or class demonstration, and give the relative numbers in each case.	4. State what animals (including frogs) are used, and give the numbers of each species.	5. State whether and in what proportion of cases the animals are in the state of anæsthesia, distinguish the case of frogs:—and also what anæsthetics are employed.	6. When not in that state, the reason why not.
ENGLAND.						
St. Bartholomew's - -	Yes.	See answer 4.	Experiments are made for both purposes. As to original research, the individual experimenters (always lecturers or members of the medical staff, in either case qualified medical men,) only can give information. Their experiments are made on their own responsibility, and form no part of the curriculum of the medical school. As to class demonstration, see answer 4.	Frogs, 20 or 30, and about half as many dog, cats, and rabbits (chiefly rabbits).	In all cases of class demonstration the animals are in a state of anæsthesia. The animals are killed at the end of the demonstrations. The anæsthetics employed are wourali, chloral, chloroform, ether.	See answer 5.
St. Thomas's - -	Physiology. The only living animals subjected to experiment in this department have been frogs.	Three or four.	All for class demonstration. In all cases for demonstrating the circulation of the blood in the smaller vessels of the body.	Frogs. Three or four in all.	In demonstrating the circulation in the web of the frog's foot no anæsthetics are used. In demonstrating the circulation in the mesentery, curare is used.	—
Guy's - - -	Yes.	These amount to from 40 to 50 a year for the purposes of class demonstration. Experiments for original research vary in number with the nature and extent of the inquiries that are being prosecuted by the physiologists, and usually average from 15 to 20 in the course of a year, taking an average of years.		Dogs, rabbits, guinea-pigs, frogs, and occasionally rats. The greater number consist of dogs, rabbits, and frogs in about equal proportion.	All experiments for class purposes, and almost invariably all those prosecuted for original research, are conducted while the animals are in an anæsthetic condition. The anæsthetics employed are chloroform, puff ball, chloral, and croton chloral. Frogs are invariably pithed prior to experiment.	Because in some instances it might be necessary to discover whether the result had been rendered nugatory or fallacious by the anæsthetic.
St. George's - -	On rare occasions frogs have been experimented upon for scientific but not for teaching purposes.	Five or six.	These experiments were all performed for private research on the part of one of the surgeons, and had no relation to the business of the school.	Frogs only.	These frogs were previously injected with curare, which recent experiments tend to prove has an anæsthetic action.	—
London Hospital and Medical College.	Yes.	Two or three.	To demonstrate circulation in frogs for class demonstration about once or twice a year. To obtain blood for examination the tails of	Frogs, newts, and human fingers, perhaps twice a year.	Frogs are curarized; newts and human beings not anæsthetised.	Because the pain is much less than the annoyance of chloroform narcosis.

			newts are snipped off and the fingers of the lecturer or class pricked with a needle.			
MIDDLESEX - -	Yes.	None last year; about a dozen the year before.	For class demonstration.	Perhaps half a dozen frogs (pithed) and the rest rabbits.	Always in the state of anæsthesia. The anæsthetics employed being chloroform, ether, or chloral hydrate. In the case of frogs the brain is destroyed before any experiment is performed.	—
UNIVERSITY COLLEGE - -	Yes, in the physiological laboratory.	If frogs are included, it is impossible to make this statement with accuracy.	For both purposes. It is possible to state with approximate accuracy, that during the year ending December 31, 1874, about seven animals were used for demonstration, and about 12 for research. In the previous year about the same number of animals was used for demonstration, and a somewhat larger number for research. In both cases frogs are not included.	Probably somewhere about 100 frogs, but it is impossible to state this accurately. About six dogs and six cats were used for research, and about six rabbits and one cat for demonstration. During 1873 a certain number of guinea-pigs were also used for research.	During the year 1874, all the mammalian animals employed were in a state of anæsthesia. This was also the case previously, but I am not able to make so positive a statement about it. The anæsthetics used were chloral, chloroform, and ether.	No statement can be made with reference to the anæsthesia of frogs,
KING'S COLLEGE - -	Yes.	Two to three hundred.	For demonstration, about 150; for original research, from 50 to 150.	Frogs, 150; newts, 20; tritons, 30; dityscus, 20; rabbits, 25; cats, 5; dogs, 10; guinea pigs, rarely; (as nearly as possible).	Generally in a state of anæsthesia; frogs, newts, &c. not so frequently, as some operations are painless. Chloral, chloroform, morphia.	Only in such cases as do not require it from the insignificance of the pain, or in those where the use of anæsthetics would interfere with the result of the experiment.
WESTMINSTER - -	Yes.	About 15.	All for class demonstration.	All frogs.	In the majority of cases anæsthesia was produced by woorara.	Because the anæsthesia would have vitiated the result.
CHARING CROSS - -	Yes.	No exact number can be given, no account having been kept; but it is small.	Almost entirely for class demonstration.	Frogs, newts, and water-beetles. Pigeons and rabbits have been used, but very rarely; not once a year. The number of frogs and newts cannot be exactly stated, for the reason previously given.	The frogs have been usually curarized; for the larger animals chloral has always been used. The newts and water-beetles have not been in a state of anæsthesia.	The only operation on these last has been the withdrawal of a drop of living blood or a minute portion of muscle, implying in such organisms no pain whatever.
ST. MARY'S - - -	As far as I know, no experiments are performed on live animals (including frogs) in St. Mary's Hospital, or in the schools and laboratories connected with it.					
QUEEN'S COLLEGE, BIRMINGHAM.	No return has been received.	- -	—	—	—	—
BRISTOL MEDICAL SCHOOL -	The experiments on live animals at the Bristol Medical School have been confined (of late years) to the drowning of two or three rabbits in each year for the purpose of class demonstration in medical jurisprudence, the use of anæsthetics in such cases being obviously superfluous.					

§ 8. Digest of Replies to Questions, &c.—*continued.*

Name of Medical School, &c.	1. Are any experiments performed on live animals (including frogs) for scientific or teaching purposes at —— or in the Hospitals, Schools, and Laboratories connected with it?	2. State as accurately as you can the number of such experiments performed in the course of the year.	3. State for what purposes such experiments are made, whether for original research or class demonstration, and give the relative numbers in each case.	4. State what animals (including frogs) are used, and give the numbers of each species.	5. State whether and in what proportion of cases the animals are in the state of anæsthesia, distinguish the case of frogs:—and also what anæsthetics are employed.	6. When not in that state, the reason why not.
University of Cambridge -	Such experiments are performed only at the physiological laboratory in the new museums under the direction of the Trinity Prælector of Physiology.	It is difficult to answer this question exactly. Probably 200, or rather more than 100 (excluding invertebrates), such experiments have been performed in each of the last two years.	Probably rather more than one half were for original research, and the remainder for class demonstration.	For research purposes, about 12 dogs, 3 or 4 cats, 30 or 40 rabbits, 4 or 5 tortoises, 1 snake, about 60 snails, 30 or 40 frogs and toads, about 12 fresh-water hydræ, during the past year. For class teaching, 4 or 5 dogs, 4 or 5 cats, 30 or 40 rabbits, and 20 or 30 frogs, during the past year.	In the case of dogs anæsthesia was always employed, being brought about by morphia or morphia and chloroform combined. In the case of cats and rabbits, anæsthesia was always used, being brought about by chloral. In the case of frogs used for research purposes chloroform was used for painful and short operations, and urari when the animal had to be observed for some considerable time. When frogs were used for class purposes chloroform or ether was used for short operations, and in other instances morphia with urari, and latterly urari alone.	In the case of the snails and the hydræ anæsthetics were not employed, because they would have interfered with the results of the experiments; indeed, it is more than doubtful whether such animals can be thrown into a state of anæsthesia. In all other cases, including frogs, anæsthetics (urari being included as such) were employed.
	It is presumed that by "experiments performed on live animals" it is intended to refer to experiments performed on animals in possession of their brain and spinal cord, where these form a part of their organization. Then, experiments on the muscles, nerves, heart, &c. of frogs previously deprived of their brain and spinal cord are not to be considered as experiments on living animals. This remark is made because by far the greater number of the experiments constituting part of the practical work of the class of physiology, and a great number of those carried on for the purposes of research, have been experiments performed on frogs and toads whose brains, and in many instances the spinal cords, had been destroyed. The returns here given are made on the supposition that such is the meaning attached to the words. If, on the contrary, "live animals" are intended to include animals whose brain and spinal cord have been destroyed, and therefore, logically, any living tissue or organ, the number of frogs given in this return would have to be increased to two or three hundred in each year, the increase belonging rather more to research than to class teaching. In these cases the brain and spinal cord was destroyed by the operation of "pithing," which causes almost instantaneous loss of consciousness, and may therefore be considered as almost painless.					
Leeds School of Medicine	No.	—	—	—	—	—
Liverpool Royal Infirmary School of Medicine.	Yes.	During the present year about 60. (The average of other years is less than this.)	About 50 of these vivisections were made for the purposes of original research. The remainder for class demonstration. No vivisections are ever allowed to be performed by students.	45 rabbits, 3 monkeys, 1 tortoise, about 10 frogs.	In every instance deep anæsthesia was produced; in warm-blooded animals by ether or chloroform, in the frog and tortoise by the same means, or by injecting chloral, or the spinal cord was divided in the neck.	—

OWENS COLLEGE.	Yes. Experiments on living animals are performed by the professor of physiology for the purpose of illustrating his lectures on practical physiology, and more rarely those on systematic physiology. Experiments on living animals are, moreover, frequently performed in the physiological laboratory of Owens College for the purposes of original research.	It is impossible to answer this question, even in an approximate manner, as no record of the actual number of experiments has hitherto been kept.	In so far as this question admits of being answered, it is so in the reply to 1.	The animals employed for the purpose of experiment are rabbits, frogs, rats, guinea-pigs, and (rarely) dogs and cats. No record has hitherto been kept of the number of animals used, and this naturally varies greatly, depending upon the nature of the inquiries which are being conducted. A considerable proportion of the animals used are killed for the purpose of anatomical investigation, and are not subjected to any experiment whilst alive.	In all cases of experiments performed for class demonstrations, *i.e.*, not performed for the purposes of original research, anæsthetics are used. When the body of an animal is to be used for anatomical purposes, and death can be caused rapidly, as by decapitation, no anæsthetic is employed. The anæsthetics and hypnotics used are the following: chloroform, administered by inhalation; morphia injected subcutaneously, followed by the inhalation of chloroform; chloral injected subcutaneously. Frogs are rendered insensible when required, by immersion of their bodies in a diluted watery solution of chloroform.	Anæsthetic and hypnotic agents are not made use of when their introduction into the system would vitiate or obscure the result of observations made to discover new scientific truths.
OXFORD: Anatomical Department Museum.	Yes, but none regularly which entail the sacrifice of life.	Not more than half a dozen per annum, upon frogs, for purpose and in manner below specified.	Experiments are sometimes made for purposes of original research, but not regularly nor every year. Experiments for purposes of class demonstration are made every year upon frogs.	Half a dozen frogs annually; and occasionally, but not regularly, small birds and mammals.	In all cases in which any pain can be supposed to be likely to be caused, anæsthetics are employed. For the purpose of showing the circulation in the web of frogs' feet, curare has been employed as it renders the animal motionless, and the experiment does not involve the infliction of pain. The anæsthetics employed in original research are chloroform or chloral hydrate.	In some lectures on respiration, live animals have been placed under a bell jar, with air drawn through it in a constant current, to demonstrate the effects of the process of respiration. Their situation is much that of a man in a well ventilated room, and no anæsthetics are needed or employed.
General Hospital (Radcliffe Infirmary) and Sanitary Laboratory, Medical Department, in the Museum.	No vivisection is ever practised in the General Hospital (Radcliffe Infirmary) in Oxford. Nor has vivisection ever been practised in the Sanitary Laboratory of the Medical Department in the Museum.					
Exeter College Laboratory.	Experiments on live animals (including frogs) are performed in my laboratory both for scientific investigation and for teaching purposes.	The laboratory has only been established for three years, and it would be impossible to give an estimate of what might be the number of experiments, supposing that certain questions were to occupy my attention, or that pupils capable of profiting by such experimental work were to present themselves. I should estimate the number of experiments on live animals, which *have been* performed during the past three years in the laboratory, as not more than 30 (ex-	About half of these experiments have been made for my own investigations solely; but an experiment made for exhibition to one or more pupils is not, in my opinion, at any time likely to be devoid of importance for a person engaged in research, or upon topics more or less illustrated by the experiment.	The animals used have been frogs in all the experiments above mentioned. It is perhaps only right that I should mention, inasmuch as I should include such organisms under the term "animals," that experiments have also been made from time to time on fish, on tadpoles, on worms, on crayfish, on insects, fresh-water mussels, and on various microscopic animals. I am not able to give an exact estimate of the number of these various animals used both in	I am not able to assert that in any case the animal employed has been in a state of anæsthesia. Many of the experiments have been such as to be unaccompanied by any of those movements which are by some persons considered to indicate pain. In other cases (frogs) the power of movement has been removed by injection of curari, which, it appears to be exceedingly probable, suspends those functions of the nervous system which are active in ourselves when	My reason for not employing such an anæsthetic as chloroform in the case of a frog is that it is easier to prevent movement either by curari or by wrapping in a cloth. It is desirable to prevent these movements both for the purposes of the experiment and on account of the injurious effect which in some cases they might produce in the mind of a student, who should look on at the experiment as at a gladiatorial spectacle. But considering what is known

§ 8. Digest of Replies to Questions, &c.—*continued.*

Name of Medical School, &c.	1. Are any experiments performed on live animals (including frogs) for scientific or teaching purposes at —— or in the Hospitals, Schools, and Laboratories connected with it?	2. State as accurately as you can the number of such experiments performed in the course of the year.	3. State for what purposes such experiments are made, whether for original research or class demonstration, and give the relative numbers in each case.	4. State whether and in what proportion of cases the animals are in the state of anæsthesia, distinguish the case of frogs:—and also what anæsthetics are employed.	6. When not in that state, the reason why not.
		clusive of some mentioned in Answer 4).		my class and by himself; but if the microscopic animals are excluded as being too numerous for computation, I should suppose that some 50 or 60 in the three years would be near the number employed.	we experience pain. In other cases the movements are the subject of the experiment.	with regard to the structure and the functions of the frog, I should say that the probability of its experiencing anything like that which we call, in the case of ourselves, pain, is so small, that I should not be anxious to apply to it those drugs which, in the case of man, remove the consciousness of pain. On the other hand, it is necessary for me to observe, that in the case of experiments with such animals as the rabbit, cat, dog, and monkey (but especially the three latter) I should in experiments not of the briefest duration, and such as would give *severe* pain to a man, employ chloroform or a similar anæsthetic on the grounds (1st) that in proportion as the structure and functions of an animal resemble those of man, there is probability that it is capable of experiencing a degree of that state of consciousness which we call pain, and (2nd) that it is undesirable for men to accustom themselves to evoke that state of consciousness when they can avoid doing so without sacrificing results which tend to the good of mankind.
Magdalen College Laboratory.	Yes, in the laboratory of Magdalen College such experiments are performed.	Exclusive of pithed frogs, from 10 to 20.	These experiments have been made for both the purposes of original research and class demonstration, but the majority for the latter purpose.	Rabbits, two dogs, a few fish, and the majority as against all the rest, frogs.	With a very few exceptions the animals were anæsthetized with chloroform; chloral, or urari.	The exceptions were a few experiments for the purposes of original research upon the influence of urari, which were instituted with the express purpose of discovering whether this drug was an anæsthetic, and which resulted in demonstrating that it possesses this power. (For details of this see "Nature," Aug. 19, 1875.)
SHEFFIELD SCHOOL OF MEDICINE.	Yes, in the School of Medicine.	Two.	Class demonstration.	One frog, one rabbit.	The rabbit in a state of anæsthesia. Not the frog. Chloroform.	In frog only; because the web is simply exposed.
UNIVERSITY OF DURHAM.	I regret that I am unable to give you the detailed information which you require, as our late Professor of Physiology Dr. Nicholson, did not perform any experiments on live animals for teaching purposes. A few experiments have been performed during the past year for scientific purposes. The animals have in all cases, frogs sometimes excepted, been in a state of anæsthesia. It is the intention of our present lecturer on physiology, Dr. Preoch, to perform experiments on live animals both for scientific and teaching purposes. As his course of lectures has only just commenced, I am unable to give you the number of such experiments. Frogs, rabbits, dogs, and cats will be used. The animals will in all cases, frogs sometimes excepted, be in a state of anæsthesia. Chloroform is the anæsthetic which will be most frequently employed.					

Royal College of Surgeons in Ireland.	Yes.	Circulation in frogs is shown three times; intestinal movements in a rabbit killed by blow on the occiput; circulation in the tail of a minnow (once).	For class demonstration only.	See reply to No. 2.	In the case of the frogs, wourara is employed.	The minnow is not put to any torture: the rabbit is quite insensible.
Trinity College, Dublin	There are no experiments performed on *living* animals in Trinity College of a kind that inflicts pain, and there are no experiments performed upon animals under the influence of anæsthetics.					
Catholic University, Dublin.	The circulation in the web of the frog's foot is annually demonstrated by Professor Cryan, for the instruction of his class, the animals (frogs) being under the influence of curara. They are subsequently killed by decapitation.	About eight.	Class demonstration; number as previously given.	Frogs only, number as previously stated.	No anæsthetic has been used.	Probable interference with the regularity and force of the circulation.
Carmichael School of Medicine, Dublin.	Yes.	Very few. Seldom more than six for purposes of demonstration; except for obtaining specimens of fresh blood for microscopic purposes.	I usually show a few fundamental experiments to the physiology class. As already stated seldom more than six, and often not so many. The number of animals used for original research varies from 0 upwards. I regret to say there are seldom any original researches being conducted, hence very few animals are ever used.	Frogs, newts, rabbits, occasionally dogs. For class demonstrations the six might be divided, two rabbits and four frogs, occasionally one dog. I cannot pretend to give any answer in the case of original research.	In nearly all. Chloral hydrate for rabbits; chloroform for dogs; frogs are generally pithed. Sometimes curara is used.	The only cases in which I have not used anæsthetics is in those where I conceive the pain to be but slight. I have never made experiments on sentient nerves which might require the absence of anæsthetics. I desire to add that all experiments are made either by myself or under my immediate supervision, and I have never known "a student" (in the ordinary restricted meaning of the term) make, or desire to make, any physiological experiment.
Petre Street Original School of Medicine, Dublin.	None at present, as the lecturers have some time ago come to the conclusion that they are quite unnecessary.	None.	None.	None.	None.	None.
Dr. Steevens's Hospital, Dublin.	Yes.	Two or three in the year.	Class demonstration.	Frogs only.	Anæsthetics always used—curara.	
Queen's College, Belfast	Yes.	But few each year for class demonstrations; occasionally larger numbers for original research.	Probably 6 to 10 frogs are used annually. Some are used alive and without injury to show the circulation of the blood in the web of the foot and in the tongue, in the classes of physiology and histology; others are decapitated in a private room, and their bodies used to show the electrical currents in muscle in the chemical class, and the textures in a fresh state in the class of histology.	For original research, rabbits, cats, dogs, mice, birds, and invertebrate animals have been used.	No anæsthetics are used.	Anæsthetics are highly dangerous to life both in men and animals, and consequently interfere with the results of physiological observations.

§ 8. Digest of Replies to Questions, &c.—*continued.*

Name of Medical School, &c.	1. Are any experiments performed on live animals (including frogs) for scientific or teaching purposes at —— or in the Hospitals, Schools, and Laboratories connected with it?	2. State as accurately a you can the number of such experiments performed in the course of the year.	3. State for what purposes such experiments are made, whether for original research or class demonstration, and give the relative number in each case.	4. State what animals (including frogs) are used, and give the numbers of each species.	5. State whether and in what proportion of cases the animals are in the state of anæsthesia, distinguish the case of frogs:—and also what anæsthetics are employed.	6. When not in that state, the reason why not.
Queen's College, Cork -	Yes.	The number depends upon the views of the lecturers for the time being of physiology, therapeutics, and medical jurisprudence, and could not therefore be accurately stated. The number is in any case very small, such experiments being resorted to only where the phenomena cannot be otherwise investigated or illustrated. Last year, for example, the total number did not exceed a dozen, including cases of poisoning.	For both purposes. Last years however, the experiments were chiefly for purposes of demonstration.	Dogs, rabbits, birds, and a few frogs. Last year the experiments made being for the purpose of determining the poisonous action of certain subsatnces, birds and rabbits were chiefly employed.	Unless in the relatively few cases where anæsthesia would interfere with the phenomena to be investigated the animals are always put into that state. The anæsthetics employed are chloroform and ethers.	The answer to this question is given under No. 5.
Queen's College, Galway	No physiological laboratory has yet been established by Government in the college. Experiments for teaching purposes are occasionally made in the classes of phy siology and medical jurisprudence.	So far as I can learn, not more than a dozen experiments involving vivisection have been made during the last year.	For class demonstration.	Frogs were the only animals used.	—	—
SCOTLAND.						
University of Edinburgh -	Experiments on live animals are performed for scientific and teaching purposes (*i.e.* for original research and for tuition) in the physiological department of the University of Edinburgh.	During the past year (the first year of office of the present professor of physiology) about 232 such experiments, for all purposes, were performed.	About 66 for the purpose of original research, and about 166 for the tuition of medical students in physiology.	A. For original research 44 dogs, about 8 rabbits, about 12 frogs, 2 cats; total 66. B. For purposes of tuition 2 dogs, 9 rabbits, about 155 frogs; total 166. P.S.—It may be stated that the professor of physiology considers the number of dogs used last year for original research to have been exceptionally high, and that of frogs exceptionally low. The animals used illustrated a course of 100 lectures to 162 medical students, and a course of practical physiology for 125 students.	A. Of the animals used for original research 4 dogs and 2 cats were anæsthetised by chloroform; 40 dogs got curara; the rabbits and frogs got nothing that could act on the sensory nerve apparatus. B. Of those used for teaching purposes all the dogs and rabbits were anæsthetised by chloroform, opium, or chloral; about 133 frogs got curara; about 23 frogs got no anæsthetic.	Animals were not anæsthetised when it was believed that an anæsthetic would render the result of the experiment equivocal.

GEONS' HALL, EDINBURGH.	formed in connexion with the class of Institutes of Medicine or Physiology taught by Dr. McKendrick.		trating the physiology of nerves and muscles, and certain points connected with the circulation.		as the animals are suddenly decapitated, and thus deprived of sensation.	
UNIVERSITY OF GLASGOW -	Yes.	Between twenty and thirty.	For both purposes. Eight or ten original experiments.	Frogs, say twelve; rabbits, six; dogs and cats, four.	All anæsthetised, except two or three. Anæsthetics:—chloroform, ether, chloral, and curari.	Two or three experiments upon sensation.
UNIVERSITY OF ABERDEEN -	No such experiments are practised here.					
VETERINARY COLLEGES.						
ROYAL VETERINARY COLLEGE	No experiments for teaching purposes are had recourse to in any department of the college. Experiments for the purpose of determining the pathology of infectious and allied diseases are occasionally adopted.	The number varies, but cannot be said to exceed 20 to 25 in a year.	For original pathological research.	Guinea-pigs and rabbits chiefly. Occasionally sheep, calves, and donkeys.	Anæsthesia is not produced in the animals which are subjected to the class of experiments named.	—
VETERINARY COLLEGE, EDINBURGH.	Yes.	About 50 or 60. The numbers vary according to the amount of original investigation done. The number of animals used for class demonstration is from year to year the same in physiological department. About 16 or 18 in pathological department.	The experiments were made chiefly for original research. Six or eight experiments are made in the course of the year for class demonstration upon frogs alone (in the physiological department). Majority of experiments made for class demonstration, two or three only being for original therapeutic research (in pathological department).	The following animals have been used on an average: 8 to 10 rabbits, 2 or 3 dogs, 2 or 3 cats, 8 to 10 white mice, 5 or 6 pigeons, and the remainder frogs and gold-fish (in the physiological department). About 10 or 12 horses, 1 cow, and 2 or 3 dogs (in the pathological department).	Nearly all the animals are in a state of anæsthesia. Some on which the actions of drugs were tried received no anæsthesia. Before class experiments on the frog it is instantaneously killed and pithed, except in the instance when the circulation of the blood is demonstrated in the foot of uninjured frogs. The anæsthetics employed have been chloroform and chloral, but latterly the hydrochlorate of chinoline has been in use, as it has distinct advantages for such animals as rabbits (in physiological department). All animals completely anæsthetised with chloroform, from the effects of which they are not allowed to recover, death being completed by opening the carotid artery. If minor operations are to be performed the ether spray is used, and animal killed immediately after (in pathological department).	In the instances where anæsthetics were not employed, it was for the reason that the use of an anæsthetic substance would interfere with the success of the experiment, as in testing the action of any drug or chemical substance on the animal, or, as above stated, in the case of the frog used for demonstrating the chief facts of muscular contractility and the action of nerve, where it was instantaneously deprived of sensibility by removal of the head and pithing.

Digest of Replies to Questions—*continued.*

Name of Medical School, &c.	1. Are any experiments performed on live animals (including frogs) for scientific or teaching purposes at —— or in the Hospitals, Schools, and Laboratories connected with it.	2. State as accurately as you can the number of such experiments performed in the course of the year.	3. State for what purposes such experiments are made, whether for original research or class demonstration, and give the relative numbers in each case.	4. State what animals (including frogs) are used, and give the numbers of each species.	5. State whether and in what proportion of cases the animals are in the state of anæsthesia, distinguish the case of frogs:—and also what anæsthetics are employed.	6. When not in that state, the reason why not.
New Veterinary College, Edinburgh.	Yes.	About half a dozen.	For class demonstration.	Frogs, horses, and donkeys.	They are always rendered unconscious by chloroform.	—
Veterinary College, Glasgow.	Yes, such experiments are performed in the physiology class at this college.	About 100 experiments altogether in the course of the year.	The great majority of the experiments made are for class demonstration; the others have been for original research or for the purpose of verifying the statements and results of other physiologists.	About 20 frogs, 2 or 3 rabbits, 3 dogs.	In all cases the animals have been anæsthetised with chloroform, or in the case of the frogs with curare, except when the experiments permitted of pithing being previously performed.	
Brown Institution - -	Yes; exclusively for the purposes of scientific research, in which I have been myself engaged.	A hundred and two during the year ending Michaelmas 1875.	All of the animals were used for experiments relating to infection, or to the action of disinfectant remedies.	Four donkeys, thirty dogs, three rabbits, sixty-five guinea-pigs.	None were in a state of anæsthesia.	The operation in every case was extremely trifling. It consisted either in opening a vessel for obtaining blood for analysis, or injecting infecting material either into the circulation, into a serous cavity, or under the skin.
	N.B.—I am informed that about half a dozen frogs were used by Dr. Klein for teaching purposes. I am unable to state the nature of his experiments.

APPENDIX IV.

PREFACE.

It has been thought best to introduce this evidence by a description of apparatus required for operations written by Dr. Brunton, which corresponds with similar directions in the "Handbook for the Physiological Laboratory," edited by Dr. Burdon-Sanderson, and other handbooks.

References are added to all extracts.

If it be alleged that although the authors do not state it, the animals were nevertheless narcotised in some of the experiments, it may be said in reply that no rule exists for the production of anæsthesia in laboratories except the operator's conscience and his convenience in manipulation; and that vivisectors sometimes are of opinion that the presence of pain is preferable to the presence of a narcotic. It may also be added that when animals have to be narcotised the writers generally state such circumstance, and the omission, therefore, adds weight to the foregoing remarks. Even when used, a narcotic may be insufficient in quantity or ineffectual in quality to prevent pain, although effective to permit of easier experimentation. The object may, moreover, be to deaden the sensory nerves during the cutting process only; and in such cases the animal awakens from its enforced sleep to the terrible consciousness of torture. Curare does not destroy pain, but only the power to express it. All these points must be remembered in reading the evidence.

It is not expected that every one of the following quotations will pass without question; but it is assumed that the entire collection will present conclusive evidence that pain is very often inflicted by vivisectors, much of which is prolonged.

The extracts are made from English books, and where the experiment was performed on the Continent it will be found that an English sanction has been given to it.

Four divisions have been made, viz.:—(*a.*) Pain; (*b.*) Prolonged pain; (*c.*) Design to teach students vivisection; (*d.*) Opinions more or less against vivisection.

A.

EVIDENCE OF PAIN.

A few of the following experiments may be said to show prolonged pain, especially in those of snake bites; but to prevent the mutilation of a consecutive series of experiments they have been retained under this head.

Lectures on Experimental Investigation.

Mode of securing Animals.—In order to determine in an exact manner what organs or parts are affected, we are obliged to make use of apparatus of various kinds; and before these can be applied to an animal it must be prevented from moving. Frogs are fastened to a frog-board by a piece of cord with a noose at the end, slipped over each elbow and ankle. The frog-board may consist of a piece of mill-board about nine inches long by three inches broad, with four slits at the sides to keep the cords in position, or of a piece of wood the same size, and from a quarter to half an inch thick, with holes, through which the cords are passed. They may be fastened by simply tying them together, or by sticking a small wooden pin into each hole, or by four screws, such as are used by fastening the wires of galvanic batteries, placed in the edges of the board. The last way is, I think, the most convenient. Rabbits are best secured by Czermak's holder and board.

[Here follows drawing of Czermak's holder, with the following key:—]

(Czermak's rabbit-holder and board.—A, the board. B, a bent piece of iron forming the upper part of the board. C, an open space through which instruments can be introduced from below to divide the spinal cord. It is generally covered by an iron plate. D is an upright rod fixed by a screw into a slit in B. F, is a forked rod, which can be moved back or forward, up or down, by the nut E. The forks are hollow, so that the ends of the holder can be passed into them and fastened by the screw *j*. H, is a bar which passes behind the incisor teeth of the rabbit. G and G are two bent bars which pass under the chin and over the nose of the animal, and are brought together by the screw *l*. From the upper end of *g′* hangs a screw, which passes between two projections on *g*, and has a mother-screw K. The screw K works against the projections on *g*, and draws the ends of *g′* and *g* together. These press on the rabbit's nose and under jaw, and keep the teeth firmly locked over the rod *h*. M M are screws for fixing the cords which confine the legs. They are a remarkably convenient sort, consisting of an outer part with a horizontal hole, and an inner ring with a stalk, on which a milled screw plays when the milled head is at the top of the stalk; the inner ring and outer holes correspond, and the cord can be easily pushed through; but when the milled head is turned, the stalk and ring are drawn up and the cord nipped between it and the outer part. The cords may either be fastened directly in the screw, or passed first through one of the holes in the edge of the board. The board should be covered with a large pad of india-rubber stuffed with horse-hair, and there should be another round pillow to put under the animal's neck.)

The best cord is strong window cord. The one end should be flattened with a hammer, and turned over so as to make a small loop, whose two sides are then firmly bound together with waxed thread. Through this loop the other end is passed, and the noose thus made is ready to be drawn tight at any moment. The other end of the cord should be cut to a point, and also bound with waxed thread, to prevent the strands unravelling. The rabbit is placed on the board, the nooses slipped over the legs and drawn tight, and the ends of each cord passed through the screw which will be nearest it when the animal lies on its back. The rabbit is then turned over, and the cords drawn through the screws and fastened. The bar *h* is then put between its teeth, and the screw *l* turned till *g* and *g′* fit tightly over its muscle, and the projecting ends of *g* fixed into the ends of *f*. Dogs may be fastened by Bernard's holder,

[Here follows drawing of Bernard's holder, with the following key:—]

(A, is Bernard's dog-holder.—*a* is a metal ring, within which a bent piece of metal, *b*, is moved up and down by the screw *c*. *h* is a straight piece, which is fastened by a screw to *a*, and can be moved nearer to or farther from a corresponding piece at *b*. These two pieces lie under the lower jaw of the dog; the bent piece *b* is screwed down on its nose, and the strap *i* buckled behind its head, which is thus firmly fixed. It may be moved back or forward by sliding the rod *d* through the nut *e*, or up and down by moving *e* on *f*, which is a strong iron rod fastened to a table or board by the screw *g*.)

(B, Brunton's holder for dogs or rabbits.—A loop of cord is tied round the upper jaw, the bar *l* passed behind the canine teeth of the dog or cat or incisors of the rabbit, and the two jaws then tied together to prevent its slipping out. This mode of fastening animals has been long used, and my modification simply consists in the addition of the forked bar *k*. After *l* is fastened in the mouth, the forked ends of *k* are pushed through holes in *l*, and fastened by the screws *m*. *k* may then be fastened to an upright bar by means of a nut in the same way as Bernard's or Czermak's holder.)

or by a simple bar of iron put behind their canine teeth. A piece of cord is first tied round the upper jaw, the bar put into the mouth, and the two jaws tied firmly over it. A split strap may be used instead of the cord. I have had a bar made with a hole at each end into which a fork of steel passes and is secured by a screw. The fork may then be fastened by a nut to an upright rod, as in Czermak's holder (Fig. 2 B). Cats and guinea-pigs may be fastened by Czermak's holder. For guinea-pigs, a little padding must be placed between g and g', in order to make them catch the head. A simple bar and cord may also be used for rabbits, cats, and guinea-pigs as well as for dogs.

. . . .

Narcotising Animals.—Narcotics cannot be given in all cases to animals on which we experiment, as their action must to a certain extent complicate that of the drug which we wish to investigate. We cannot use them when we are observing what are the general symptoms which a medicine produces. But when we are investigating its action on particular organs we may often use them, not only with safety but with advantage, when they have no action on the particular organ which we are studying, or so little that its disturbing influence is more than compensated by the diminished muscular action and consequent ease in performing the experiment which narcotics produce. It is almost unnecessary to say that, in all cases which admit of it, narcotics should be used, as we have no right to inflict any unnecessary pain, although we may be justified in taking the lives of the lower animals in order to preserve the more valuable life of man, either by supplying him with food by means of those killed in the slaughterhouse or by obtaining the knowledge which shall enable us to cure disease by means of those killed in our experiments. The narcotics which we use are opium and chloral. Chloroform is inadmissible, as its administration generally seems to cause dogs more pain than the experiment itself, and rabbits are very easily killed by it. . . . . . .

When we wish to render the animal absolutely motionless, or to observe what effect any drug will produce after the motor nerves have been paralysed, we give curare. .

. . . .

Curare may be obtained from Messrs. Hopkin and Williams, New Cavendish Street, London, or from Bruckner and Lampe.—*Dr. Brunton, British Medical Journal,* No. 542, pp. 321 and 322.

An experiment, illustrated by a drawing, shows a living frog strapped down to a board, its sciatic nerve dissected out, bared, and brought out of its body from its thigh to its loins, and attached to a galvanometer, after which strychnia is introduced under its skin, and a result from the action of the tortured nerve is shown on the needle of the instrument.—*Dr. Radcliffe, Lancet,* No. 2,061, p. 227.

If the sciatic nerve of a rabbit be divided in the ham, and the end which is in connection with the brain be dissected out and laid across the poles of a galvanic cell, the animal screams with pain and strains with convulsive movements when the circuit is closed or opened. Before the time when the portion of the nerve which is included in the circuit is paralysed by the current, the screams and convulsions happen equally at the closing and opening of the circuit, and it is immaterial whether the positive or the negative pole be in the position next the brain. After the time when the portion of nerve which is included in the circuit is paralysed by the current the screams and convulsions are present at the closing of the circuit and absent at the opening when the negative pole is in position next to the brain, and absent at the closing of the circuit and present at the opening when the positive pole is in the position next the brain. Pain and convulsion, that is to say, come together and go together. In a word, there is reason to believe that the electrical changes which a sentient nerve experiences in the production of sensation are the exact equivalents of the electrical changes which a motor nerve experiences in the production of muscular contraction.—*Dr. Radcliffe, Lancet,* No. 2,067, p. 409.

Through a fistulous opening into the stomach of a dog Bernard introduced, whilst digestion was going on, the hind legs of a living frog. The legs were dissolved away, the animal continuing all the while alive, and living for some time even after the experiment was completed. I have repeated this experiment myself and obtained a similar result. It proves unquestionably that the stomach has the power of dissolving living substances. .

. . . .

I performed an experiment substituting the ear of a rabbit for the hind legs of a frog. Whilst my dog with a fistulous opening in its stomach was at a period of full digestion, I carefully introduced through the cannula the ear of a vigorous rabbit and held it in position with the hands so as to avoid mechanically injuring it or producing congestion by obstructing the flow of blood through its vessels. At the end of two hours the ear was withdrawn and several spots of erosion, some as large as a sixpenny-piece, were observed on its surface, but nowhere was it eaten completely through. On being replaced for another two hours and a half, the tip, to the extent of about a half or three quarters of an inch, was almost completely removed, a small remnant of it only being left attached by a narrow shred to the remainder of the ear. The gastric juice seemed to act like a strongly corrosive material, making first a number of ulcerated-looking spots through the skin and afterwards extending its action more rapidly through the central parts of the ear. A rather profuse hæmorrhage took place, especially towards the latter part of the experiment. My own fingers became moistened with gastric juice that escaped by the side of the ear, and afterwards felt sore or tender as if the skin had been slightly acted on.—*Dr. Pavy, Lancet,* No. 2,070, p. 492.

The Parisian Correspondent describes his attendance at a meeting of the Academy of Sciences, and says:—These phenomena occur even when a drop of ammonia is inserted into the eye of an animal, and whilst the organ is strongly closed during the paroxysm of pain which ensues.—*Lancet,* No. 2,037, p. 298.

Experiments were made on small animals. The spinal cord was artificially inflamed by having a thread passed through it. The appearances found were contraction of the axis-cylinders, subsequent fissiparious division of the contracted portions, and the formation of pus from these. The nerve cells were affected with granular or "œdematous" degeneration. The neuroglia was somewhat increased, but not to a great extent. The perivascular lymphatic spaces of the surrounding pia mater were filled with lymph-corpuscles. One or two cases were quoted in confirmation of the facts.—*The Doctor,* October 1st, 1875, p. 195.

Mr. Bert has been instituting a series of experiments in illustration of "the phenomena and causes of the death of fresh-water animals when plunged into sea-water."

. . . .

A frog, when immersed in sea-water, is much agitated, and exhibits signs of pain, unless he can keep his muzzle above the surface. When all signs of sensibility have disappeared, the nerves and muscles are still found to be excitable, and the heart, filled with dark blood, is still seen to beat spontaneously. . . . . .

. . . .

The animal is found to have lost from one-fifth to one-third of its weight, the loss being chiefly borne by the muscles, which present a continuous or durable contraction like a kind of cramp.

Frog lived one hour in sea-water.—*Edinburgh Medical Journal,* 1871–72, p. 473.

By a new method of operation, a description of which is given in the original, they were enabled to remove the first thoracic ganglion without injury to the pleura, and in consequence, never observed pleuritis, as is common in the other methods of operation, and as said by some to depend upon the extirpation of the said ganglion.

On the contrary neither increase of the temperature of the ear, nor of the fore foot, or the opposite side operated on were missed, also the oculo pupillary phenomena will be the vascularisation of the conjunctiva as occurs after section of the sympathetic in the neck. Rotatory movements were absent.—*Journal of Anatomy and Physiology,* November 1874, p. 213.

For the production of coughing the author employed mechanical stimulants, feathers, pinching, teasing, squeezing with forceps, chemical irritants (common salt and ammonia), thermal (ice) and electrical stimuli were employed. [For these experiments on cats and dogs, it is said, the animals "in no case" were narcotised.]—*Journal of Anatomy and Physiology,* November 1864, p. 218.

Blindness of the opposite eye and paralytic dilatation of the corresponding pupil can be produced, while stimulation of the same spot is followed by strong and continued contraction of the pupil.—*Journal of Anatomy and Physiology,* February 1875, p. 210.

App. IV.

Having found in a large number of experiments on the effects of various agents on the temperature of the body and the generation of heat where the effects of muscular exertion had been set aside by the injection of woorara there was a constant and nearly equable fall of temperature beginning from the period of narcosis after antecedent convulsive movements, he determined to follow out by careful experiment the action of the woorara alone. . . . .

Another series of experiments were made on animals (principally dogs) in which fever was excited by the injection of pus into the veins, and it was found that even in this state the temperature was lowered by the action of woorara to the normal average or even below it.—*Lancet*, No. 2,510, p. 516.

Nothnagel states that he found the method of injecting chromic acid which he originally applied in order to determine the function of the convolutional centres inappropriate for experiments on these deeper seated centres; and he has employed instead a little cannula and trocar, from the extremity of which by pressure on a lever in the handle, small diverging arms could be made to protrude, and by rotation the thalamus could readily be entirely broken down. The powers of motion and sensation in the animal were then carefully tested, whilst an examination after death revealed the precise nature of the injury inflicted. The trocar was always introduced at the side of the head, and passed through the cornu ammonis and a part of the hemispheres.

. . . . .

He states as his final results that destruction of the optic thalami causes neither motor paralysis nor cutaneous anæsthesia, but that his experiments support the view of Meynert, namely, that motor processes take place in the optic thalami which are caused or excited by sensory impressions.—*Lancet*, No. 2,682, p. 135.

His experiments were conducted on dogs and rabbits fully under the influence of curare. A bent glass tube was inserted into the ductus communis choledochus in a large curarised rabbit, in which artificial respiration was maintained. He obtained at the commencement of an experiment lasting about half an hour one drop of bile in every seventeen seconds . . . .

Compression of the vena portæ, or of the hepatic artery, or of both together, caused an immediate diminution of the quantity of the secretion; but after some time, though the compression was continued, the liver recovered its activity to some extent. A rabbit which yielded one drop of bile in about twenty-four seconds before compression only yielded one drop of bile per seventy seconds after; and a dog previously giving one drop in thirty seconds only gave one per eighty or ninety seconds after compression. Ligature of the thoracic aorta just above the diaphragm reduced the secretion in a dog from one drop in seven seconds to one in fifty. Ligature below the cœliac axis raised the rapidity of the secretion from one drop in eight seconds to one drop in three seconds in a rabbit.—*Lancet*, No. 2,602, p. 56.

In the section on the Formation of Sugar in the Liver, Mr. Dalton gives the results of his experiments performed in 1869. He then found that if a portion of the liver of a dog was excised whilst the animal is living and immediately cut into thin pieces and thrown into boiling water. . . . —*Lancet*, No. 2,532, p. 324.

This view has been supported by two experiments intended to show—(1.) that bile pigment can be produced artificially from the bile acids by the action of concentrated sulphuric acid; and (2.) that colourless biliary acids, when injected into the veins of dogs, are converted in the blood of these animals into bile pigment. These experimental results are still the subject of much discussion. They have been controverted by Kuhne, Hoppe, G. Harley, &c., but confirmed by Stædeler, Neukaunn, Folwarczny, Röhrig, &c. —*Dr. Murchison, in Lancet*, No. 2,642, p. 537.

The animals were the dog and the frog; and the mode of experimentation was that the mean rapidity of the blood in the carotid and crural arteries and in the crural vein was ascertained; the sciatic or crural nerve was then dissected out and divided where it leaves the pelvis, yet so that both extremities could be easily subjected to the action of electric currents. The animals experimented on were either narcotised by the injection of morphia, or poisoned with woorara till the voluntary muscles were completely paralysed, artificial respiration being maintained in the latter case. It was not forgotten that, under the full toxic influence of woorara, paralysis of the vaso-motor nerves takes place.—*Lancet*, No. 2,528, p. 192. [Observe, curare is not an anæsthetic.]

By the investigations of Bernard and Brown-Séquard it has been established that the contractile elements of the blood-vessels are presided over by motor nerves. These are in consequence named vaso-motor nerves. . . . . . .

The largest vaso-motor nerve in the body is the great splanchnic nerve. It presides over the vessels of most of the abdominal viscera. It is sometimes necessary in physiological experiments to paralyse the blood-vessels of the body generally. This is readily done by dividing the cervical portion of the spinal cord at some little distance below the medulla oblongata. If, after the section, we desire to stimulate the vaso-motor nerves generally, we require to place two electrodes in the cervical portion of the cord, one on a level with, say, the third, the other on a level with the fifth cervical vertebra. The contraction of vessels produced in this way may be readily seen in the frog. I have injected $\frac{1}{2000}$ gr. of curare under the skin to paralyse the voluntary motor nerves, and so get rid of spasm of the voluntary muscles when we stimulate the spinal cord. I stretch the web, tie threads round two neighbouring toes, and fix them in slits on either side of a triangular window in a piece of cardboard. The back is uppermost. Two common sewing needles fixed in a piece of gutta-percha are pushed between the scapulæ into the spinal cord.

. . . .

In performing this experiment it is necessary to beware of giving too large a dose of curare. A powerful dose paralyses not only the voluntary motor but also the vaso-motor nerves. Do not give more than $\frac{1}{2000}$ gr.—*Dr. Rutherford, Lancet*, No. 2,525, p. 69.

If intense myosis be effected by the instillation of calabar bean into one eye irritation of the central extremity of the divided sympathetic in the neck produces no effect, for the sympathetic is paralysed by the bean; but if a current of electricity be passed across the eye, the electrodes being placed on opposite sides of the cornea, immediate dilatation can be induced, the muscular fibres being then directly called into action. A similar proof of the existence of a dilatator was formerly furnished by Hirschmann after the pupil had been made to contract with nicotine.—*Lancet*, No. 2,421, p. 127.

Dr. B. W. Richardson read a paper "On some effects of extreme cold on nervous action." This was a continuation of his experiments in relation to the freezing the centres of the nervous system. He explained that frozen frogs do not respire during insensibility.

. . . .

Freezing the brain necessarily produced a gradual slowness of the circulation, and even entire cessation of the heart's action.

. . . .

Lastly, he referred to the effects of freezing and rapidly thawing the skin of certain regions of the body, especially in birds, which in them caused extreme irregularity of movement and other signs of nervous disturbance.—*Lancet*, No. 2,348, p. 292.

M. Cohnheim's first experiments were performed on the corneæ of frogs. Inflammation was excited by touching them in the centre with a point of nitrate of silver, the contact being maintained sufficiently long to destroy the epithelium completely and to affect the corneal tissue.

. . . .

On repeating these experiments on the rabbit similar results were obtained. . . . .

His next experiments were made on vascular parts, and he chose the mesentery of frogs poisoned with woorara. Sufficient inflammation was excited by merely exposing the membrane to the air, which produced first hyperæmia, and after the lapse of twenty-four hours the exudation of a thin dull-grey gummy layer or fibrinous pseudo-membrane.—*Lancet*, No. 2,329, p. 506.

Threads are passed behind the common innominate and left subclavian arteries of a rabbit and arrangements made by which these threads may be tied and untied in a moment. On tying the ligatures the animal was violently convulsed, on untying the ligatures about sixty seconds later the convulsions, which were then raging at their height, were instantly brought to an end . . . .

In this experiment the subclavian arteries of a rabbit are tied at their origin and a ligature is also placed around the arch of the aorta a little beyond the opening of the left subclavian artery. The ligatures, that is to say, are so placed as to bring about a result which is the very opposite of that which was secured in the last experiment. In that case the blood was cut off from the head and neck and the circulation confined to the trunk and limbs; in this case the blood is cut off from the body and limbs, and the circulation confined to the head. In this case, that is to say, the vessels of the brain medulla oblongata, upper part of the spinal cord, and the cervical ganglia of the sympathetic nerve, receive more than their proper share of blood, for all the blood of the body is diverted in this direction, while the rest of the spinal cord and the thoracic and abdominal ganglia of the sympathetic nerve receive no blood at all. And what is the result? The result is paralysis of the parts behind the ligatures without convulsion. In one or two instances the paralysis was preceded by trembling, but in no instance was there convulsion or anything approaching to convulsion. It was ascertained also that this absence of convulsion was not due to paralysis of the spinal cord from want of blood, for on compressing the carotids so as to prevent the flow of blood through these vessels the animal was instantly seized with violent convulsion.—*Dr. Radcliffe, Lancet*, No. 1,908, *p.* 288.

Solution of an alkaline sitnate (from one to ten per cent.) were injected under the skin of the back or thighs of frogs. One of the sciatic nerves was then cut through; and tetanus was induced by means of strychnia. After this had lasted from one to six hours, the thighs were separately broken up into small pieces and rubbed up with water. *Dr. Gscheidlen, British Medical Journal*, No. 682, p. 118.

Dr. Lauder Brunton has made some very interesting experiments as to the action of chloral. He finds that, after large doses, the temperature falls till it can no longer be measured by ordinary clinical thermometers. Having found out what dose would kill an animal when exposed to the air, he gave this quantity to two similar animals, wrapping one up in cotton wool. The one so wrapped up survived, while the other died. Then he found out the dose which was lethal after wrapping up in wool, and gave that to two similar animals, wrapping one up in wool, and putting the other in a warm chamber. The one in wool died, the other recovered. A larger dose still was fatal to the one in the warm chamber. These experiments throw much light upon the action of chloral hydrate.—*Dr. Fothergill, British Medical Journal*, No. 680, p. 46.

A young man who wore red socks, having been attacked by a very acute and painful vesicular eruption on both feet, M. Tardieu attributed his affection to the red colour of the coralline dye. The substance in question having been separated by M. Roussin, the chemist, and injected under the skin of a dog, a rabbit, and a frog, which died from its effects, it was concluded to be a violent poison, and subsequently fell out of use as a dyeing agent. Contradictions of this statement, however, were soon forthcoming. M. Laudrin, a veterinary surgeon, asserted that he had administered coralline to dogs and cats without observing any subsequent ill effect. He had had positive proof of the absorption of the coralline and of its purity, since he had been able to collect it in the lungs of the animals, and to dye silk with it. Dr. Guyot confirmed these experiments, and came to the conclusion that coralline was not poisonous, even in large doses, and that it may be safely used in dyeing, provided that it be not mixed with poisonous substances.—*British Medical Journal*, No. 719, pp. 467 and 468.

Hieberg finds that when the epithelium is scraped off the surface of the cornea in the frog, fowl, or rat, it is reproduced only at the edge of the denuded part and never from any isolated centre on its surface.—*Journal of Anatomy and Physiology*, 1871–72, p. 247.

Bernard investigates the action of temperature by placing birds and rabbits in cages heated by a lamp or surrounded by a double metallic case containing a hot solution of sulphate of soda.

When the animals are thus exposed to a dry heat of 150° F. the respirations become quick and tumultuous, the temperature of the body rises, the heart beats quickly, and after a little time stops suddenly if the temperature be high enough. The necessary temperature is sooner reached in birds than in rabbits. It rose in birds to 122°, in rabbits to 115° F., Rigor mortis came on quickly, and both arteries and veins contained black blood.—*Journal of Anatomy and Physiology*, 1871–72, p. 236.

A few days ago I had the pleasure of assisting at several experiments of the highest interest, which Dr. Brown Séquard conducted at his laboratory of the Ecole Pratique.

. . . .

The experiments which M. Bernard has performed on the circulation of the blood are of great interest. Amongst other facts and inferences the following may be briefly related. Circulation is accelerated or slackened according as such and such a nerve is operated upon. In one of the experiments the following facts were observed. A dog was submitted to the action of woorara. When quite motionless, respiration and circulation continuing, the extremity of one ear was cut off, and the quickness with which the drops of blood fell one after another served to note the speed of circulation. A glass tube was then introduced into the submaxillary gland so as to gather the secretion. The great sympathetic was then set bare in the neck, as also the sciatic nerve in the posterior region of the thigh. The cervical string of the sympathetic was then cut, and then the blood was seen to flow much more rapidly, the drops quickly succeeding each other. At the same time a flow of saliva from the submaxillary gland into the tube was observed. Just then, however, on galvanising the upper end of the great sympathetic, the blood diminished and finally ceased running, through the contraction of the small arteries of the ear, the contraction sometimes going so far as completely to obliterate the arteries. These phenomena changed as galvanisation of the sympathetic was suspended.—*Lancet*, No. 2,550, page 63.

Their experiments were performed upon for the most part 20 curarised animals.

. . . .

At the commencement they found not unfrequently that a stimulus which in one animal excited the most violent uterine contractions, in another was apparently wholly inoperative, and this not only in animals of different genera, but in those of the same species. In rabbits, for instance, it sometimes happened that the slightest mechanical stimulus called forth active contractions, whilst in another animal no response occurred to the strongest electrical currents. They find that the animals best adapted to exhibit the movements are young but sexually mature rabbits which have not yet been impregnated. In these the uterus, when the abdominal cavity is laid open, appears as a flat, band-like, pink-coloured organ, at perfect rest, and but rarely exhibiting spontaneous movements. Their first experiments were made to determine the effect of arrest of the respiration. Krause, Mayer, and Basch have all shown that asphyxia induces movements of the intestines; but it has not hitherto been shown that a similar effect is produced upon the uterus. Oser and Schlesinger's experiments, however, show that in from ten to thirty seconds after suspension of the respiration contractions are perceptible, commencing from the tubæ and cervix, which in a few seconds more extend over the whole uterus. This organ becomes pale, cylindrical, and rigid, and moves downwards and towards the middle line; the cornua raise themselves in an arched manner, and, intercoiling, almost form a ball. The contractions increase in vigour with continued arrest of the respiration for some minutes. In a second set of experiments the effects of compression of the aorta were investigated, and it was ascertained that general contractions of the uterus occurred in a period varying from eighty to one hundred and twenty seconds after.

. . . .

Küssmaul and Tenner long ago described a somewhat similar experiment, but gave a different explanation of the phenomena observed, In a pregnant rabbit they exposed and compressed the carotids and vertebrals. Extrusion of the fœtuses occurred, but it was accompanied by convulsions, and they attributed the delivery to these rather than to any contractions of the uterus. M.M. Oser and Schlesinger further found that, after section of the spinal cord in the cervical region, the contractions of the uterus no longer occurred more rapidly after arrest of the respiration than after compression of the aorta, in each case supervening in about the same space of time, that is to say, in about one hundred seconds. After section of the cord, neither general loss of blood nor arrest of the flow of arterial blood to the brain produced any perceptible contractions.

. . . .

The authors of the paper do not attempt to fix the situation of the centre for the uterine movements, but they point out that their experiments prove that it lies at a higher point than that at which they divided the spinal cord, namely, between the occiput and atlas; and they think it is probable that it occupies some part of the medulla oblongata. At all events, it is unlikely that it is situated in the spinal cord, since the experiments of Küssmaul and Tenner and Schiffer show very clearly that the circulation of dyspnœic blood (a term that implies no theory as to whether the phenomena produced are due to the absence of oxygen or the presence of carbonic acid) through the cord is not followed by any symptoms of irritation, as by convulsions, but by rapid paralysis of the posterior extremities, the paralysis appearing in the course of a minute or a minute and a half.—*Lancet*, No. 2,551, p. 87.

Professor Cyon gives the following results of experiments made upon the above point. Dogs and rabbits were used, some under the influence of curare during the experiments, and some not. 1. The uterine plexus is the most important, if not the only motor nerve which can produce effectual movements of the uterus by the irritation of its peripheral ends. Irritation of the central ends only gave rise to severe vomiting. 2. Irritation of the central ends of the first two sacral nerves produces in a reflex way powerful uterine movements which cease after the uterine plexus has been cut through. Irritation of the peripheral nerves gives rise to powerful contractions of the bladder and rectum. 3. Irritation of the brachial, crural, median, sciatic nerves, etc., give rise to no peristaltic movements of the uterus, but only causes a slight rigidity and paleness. 4. The effect of the irritation of these nerves disappears if the aorta has been previously compressed, but irritation of the central ends of the sacral nerves still causes, even after the closure of the aorta, peristaltic movements of the uterus. 5. Suffocation through continued interruption of respiration causes powerful peristaltic movements, probably through direct excitation of the involuntary muscular fibres by the accumulation of carbonic acid gas.—*British Medical Journal*, No. 717, p. 405.

These reasonings have been confirmed by certain experiments of M. Bernard, who found that, when an incision is made into a lobe of the liver in a living animal, the blood may be seen to jet from the mouths of the hepatic veins during the movements of expiration, but to return sucking in air with it at each deep inspiration, so that the animal soon dies from the passage of air into the heart.—*Dr. Charles Murchison, British Medical Journal*, No. 696, p. 567.

Dr. Hertzmann says that by continuous administration of lactic acid to dogs and cats, rickets, firstly, and then osteo-malakia may be caused, whilst in rabbits and guinea-pigs osteo-malakia may be caused without rickets occurring. Lactic acid, he says, causes rickets as long as the animal is young, and osteo-malakia when it is older.—*The Doctor*, May 1st 1874, p. 81.

He cut down upon the splanchnics in dogs and rabbits from behind, and divided them without opening the peritoneum. After section of both great splanchnics the blood pressure fell greatly, while the rapidity of the pulse increased.

. . . .

Strange to say, in some animals which survived the operation, when the blood pressure was again observed after some days interval, it was found to have attained a degree as high as it had been before division of the nerves.

. . . .

On irritating the peripheral end of the divided splanchnicus major, or the central ends of any of its roots, the blood pressure always rose, and with few exceptions slowing of the pulse resulted. The latter was much less marked when the vagi had been previously divided.—*Journal of Anatomy and Physiology*, 1869, p. 211.

He has found that after division of intestinal nerves in dogs a large secretion of watery fluid into the intestines results. In a large healthy dog, which had fasted for twenty-four hours, he exposed a knuckle of bowel, and put four ligatures round it; these were separated from each other, so that the three portions of intestine, each about fifteen centimetres in length, were included within the ligatures. He carefully isolated and divided the nerves supplying the middle ligatured portion, taking care to avoid injury to the vessels. He closed the wound in the abdominal wall, and allowed the animal to remain at rest.

. . . .

In one dog a hundred grammes of fluid were found in the intestine three hours after the operation; and in another dog, killed eighteen hours after, two hundred and twenty-five grammes were present.—*Journal of Anatomy and Physiology*, 1869, p. 214.

Mr. Joseph Michon records an experiment which produced results different from those heretofore recorded. He removed the superior cervical ganglion of the sympathetic in the common cock.—*Lancet*, No. 2,218, p. 238.

In the last number of the American Journal of Medical Sciences we find one more added to the many theories that have been advanced to explain the uses of the cerebellum. Dr. Mitchell, an able experimenter, who states he has been studying the subject for six years, ... obtains the following results in pigeons, on which he had practised both the ablation of the organ, and the application of intense cold by means of Richardson's spray apparatus. After ablation he found, in accordance with the observations of other experimenters, that if the wound were deep convulsions invariably occurred, together with a tendency to backward movements, and that immediately succeeding, or even accompanying these, was an indescribable confusion of movement, the animal staggering, &c., and exhibiting what is commonly described as an apparent want of co-ordination.—*Lancet*, 2,393, p. 57.

At a recent sitting of the Parisian Academy of Medicine, Mr. Colin sought to demonstrate with the aid of anatomical preparations, that in man and the higher animals the auricular systole precedes the ventricular in the action of the heart, just as it occurs in the lower animals. He asserted that conviction of this fact may be obtained by taking certain precautions in experimenting on the higher animals. If the animal be carefully bled to avoid disturbance of the cardiac circulation, and if artificial respiration be properly kept up, it will be clearly seen that the contraction of the heart begins at the auricles. The speaker undertook to perform and show the experiment whenever called upon to do so. [A readiness to repeat "whenever called upon" shows a bad tendency of experimentation.]—*London Medical Record*, 1874, p. 306.

Let us first take under review the action of ozone on living animals. If a warm blooded animal be placed in a glass chamber, and be subjected to a stream of ozonised air, the oxygen of that air having been ozonised to the twelfth part and the influence of carbonic acid being entirely excluded, special physiological phenomena are quickly displayed. The first sign or symptom is an irritability of the mucous surface of the nostrils and of the conjunctivæ; there is often free secretion of saliva, and even profuse sweating in those animals that exhibit sweating; there is also thirst, and dryness of the tongue and nostrils. These symptoms are succeeded by great rapidity of respiration, and soon by violent action of the heart. When the chest is auscultated in this stage there is always dry bronchial breathing, and a whistling sound, as in the first or preliminary stage of acute bronchitis in the human subject. The effect of the ozone being sustained, cough manifests itself, followed by secretion of frothy fluid from the bronchial surface; this is equivalent to the congestive stage of bronchitis. Finally, there is lividity of the skin of the nose, of the nostrils, and of the lips, great coldness of the surface, gasping respiration, jactitation, and death, the death being often sudden. This may be said to resemble most perfectly the exudative stage of bronchitis. This order of symptoms, or phenomena as they perhaps had better be called, has been recognised by all experimentalists; it has been pointed out with particular care by Dr. Richardson, and my own experiments have been attended with a corresponding result. There is, however, a remarkable difference in the periods of the phenomena noticed in different animals, their order, nevertheless, being maintained in each case in which they are manifested. Guinea-pigs are peculiarly susceptible of the influence of ozone; these animals die in an atmosphere saturated with ozone usually in about an hour and a quarter, presenting with great exactitude the order of symptoms I have described above. Rabbits live longer than guinea-pigs, exhaling water from the lungs much more freely, and also micturating with greater freedom. Rats die very rapidly. Mice exhibit a greater tolerance. Pigeons resist the effects of ozone much longer than guinea-pigs, and may readily be taken out of the chamber in which they have been confined with guinea-pigs, apparently but little inconvenienced, at the period when the guinea-pigs are dead. If when just removed the chest is auscultated, the breathing, however, is found to be particularly sharp, dry, and cooing, the action of the heart being amazingly rapid, reaching even 240 beats in the minute, and the respiration being from 90 to 100 in the same time. Pigeons removed altogether from the ozone, when in this condition will frequently exhibit the third stage of obstruction to respiration and die. Frogs seem to have the power of resisting the influence of ozone permanently, if they are allowed free access to water.—*Dr. Day, Lancet*, No. 2,317, pp. 124, 125.

In order to prove the truth of his theory, he immersed two frogs in solutions of nicotine, which caused complete prostration or paralysis of motion, and the animals died paralysed in twenty-three minutes. Others he placed in solutions of strychnia, which produced tetanic effects of that drug, and caused death in four minutes. He then placed two others in a compound solution of the two poisons; the first frog lived in the compound solution forty-seven minutes, at the end of which time it died; the second frog was kept in the solution ten minutes, and then taken out, but after its removal from the liquid, in thirty minutes it was seized with the tetanic spasms of strychnia in the form of emprosthotonos, but ultimately recovered.—*Dr. Part, Lancet, No.* 1,961, p. 310.

"An experimental inquiry into the mode of death produced by aconite," by Dr. E. R. Harvey, was next read. The author's experiments, which were performed on dogs, rabbits, and frogs, went to prove that aconite acts first on the nerves and then on the muscles, killing by its action on the heart.—*Dr. Michael Foster, Lancet, No.* 1,923, p. 20.

Frogs introduced into a weak solution containing aniline died in periods varying from a quarter of an hour to two hours and a half, and death was also caused by the introduction of aniline into the mouth or into a wound in the back. Rabbits were also poisoned by this substance, a small animal being killed by fifty drops in six hours and a quarter, and a larger one by a hundred drops in four hours. In all the animals experimented upon violent clonic and tonic spasms ensued after the application of the aniline, and continued almost uninterruptedly till death.—*Lancet*, No. 1,994, p. 470.

Busch finds that sensibility is so much impaired in frogs poisoned by strychnia that pinching the animal's toes, or burning the central end of the divided sciatic nerve, may be performed without being followed by a reflex action.—*Journal of Anatomy and Physiology*, 1873, p. 399.

The four experiments now to be described are, as regards their results, merely confirmatory of those recorded by other investigators; but in their mode of performance some variations have been made from the methods usually followed, so as to show as clearly as possible the total inability of strychnia to act through the nerves. The experiments were performed on frogs, animals which possess the two-fold advantage of being very sensitive to the action of strychnia, and of surviving for a considerable time arrestment of the circulation.

Experiment 1.—A ligature was placed round the heart of a frog at the auricles. A solution containing the one-fourth part of a grain of strychnia was then injected into the stomach by means of a tube passed down the œsophagus. Thirty-five minutes after the injection the animal was able to leap about vigorously; fifty minutes after the injection it was still able to move its limbs although feebly; in five minutes more all movements had ceased.

. . . .

Experiment 4.—A ligature was placed round the heart of a frog at the auricles. One and a half grains of extract of nux vomica, mixed with fifteen minims of water, were then injected into the stomach by means of a tube passed down the œsophagus. Half an hour afterwards the animal was leaping about quite unaffected by the poison. The cranium was now cut through immediately behind the eyes with a pair of scissors, and a piece of extract of nux vomica was applied to the exposed nervous matter.

. . . .

Experiment 5.—The apex of the ventricle of a frog's heart was cut away. An opening was then made in the anterior abdominal vein, and a strong solution of extract of nux vomica was injected into the vein in an upward direction, that is, towards the liver and heart. . . .
. . Twenty-six minutes after the injection the animal was able to leap about; forty-three minutes after the injection it was still able to move its limbs. In a few minutes more all movements ceased.

. . . .

Experiment 6.—The greater part of the ventricle of a frog's heart was cut away. After allowing the blood to be expelled to as great an extent as possible, the remains of the heart were excised. The articulation of the lower jaw on each side was then cut through in order to facilitate the next part of the operation, which consisted in cutting through the cranium with a pair of scissors immediately behind the eyes. To the part of the brain thus exposed a piece of extract of nux vomica was applied. In about three minutes afterwards the action of the poison began to manifest itself. The muscles of the throat were first affected with spasm. The anterior extremities then became violently tetanised and directed upwards on each side of the head.—*Dr. Spence, Edinburgh Medical Journal*, July 1866, p. 44.

The following inquiry formed part of a graduation thesis given in by me to the University of Edinburgh on the 5th July 1873, entitled, "Erythroxylon Coca, with an "experimental inquiry into the physiological actions of "cocaine, theine, caffeine, &c., &c." The experimental research was conducted in the Physiological Laboratory of the University, and I have gratefully to acknowledge much kind assistance from Dr. M'Kendrick.

Upwards of one hundred experiments were conducted on different living animals, chiefly frogs, mice, rabbits, and cats. . . . .

The $\frac{1}{16}$ gr. of theine dissolved in 20 minims of water was injected under the skin over the back of a healthy middle-sized frog; almost immediately afterwards the respirations, which normally had been 80, were increased to 120 per minute. Seven minutes afterwards the respiration had diminished to 80 per minute.

The frog was now distinctly sluggish in its movements. It made attempts to leap, but did so feebly. When placed on its back it recovered its normal position with difficulty. When its toes were pinched with a pair of forceps it drew up its leg. . . . . . .
Two minutes after these symptoms were increased, and in three minutes more the limbs were very weak, and the animal lay on its belly without their support. When placed on its back the frog was unable to recover its position, but lay there with its limbs drawn up, and when the skin or toes were pinched the limbs were moved but sluggishly. The respirations had diminished to 40 per minute. Five minutes later the frog still lay motionless on its back with its limbs extended. All four legs were completely paralysed, and they remained in whatever position they were placed . . . .
The frog remained in this prostrate condition for eleven minutes, when slight spasmodic movements were observed in the limbs. Four minutes later it made feeble attempts to move its legs, and when its toe was pinched it drew them up. Four minutes afterwards, the animal gave a very feeble leap, and tried to crawl along the table . .
Eighteen minutes afterwards the frog jumped readily, especially if it was irritated. It croaked vigorously when touched, and in half an hour it was apparently in its natural state, with the exception of looking feeble . .
If smaller doses be given similar symptoms ensue, but they are less violent and less rapid in proportion to the amount.

. . . .

The $\frac{1}{12}$ gr. of theine, dissolved in 10 minims of water, was injected under the skin over the back of a white mouse weighing 3 drachms. For fifteen minutes no effects were observed. When its tail was pinched, it uttered a cry, which it did before the drug was administered. . .
It could now only crawl along the table, but could not run.
. . Five minutes later the animal lay with its limbs occasionally kicking. . . . . .
The under surface of the body, the feet, legs, and mouth were much congested. [Duration of experiment about 30 minutes.] . . . . In many instances the animal has tetanic spasms and opisthotonos.

. . . .

The left femoral artery of a healthy middle-sized frog was tied, and $\frac{1}{12}$ gr. of theine dissolved in 35 minims of water was injected under the skin over the back. In ten minutes the animal was almost prostrate. It lay on its back, but was still able to contract its limbs when they were pinched, which both did with equal strength, the left leg being perhaps somewhat more sluggish than the right. Fifteen minutes later the frog was apparently dead. The head was amputated; on irritating the upper portion of the cord with the electrodes of a weak Faradic current, the two limbs contracted powerfully, and apparently with equal strength.

. . . .

The heart of a healthy middle-sized frog was exposed by carefully dividing the sternum with a pair of scissors, and a ligature passed round its back and tied so as to interrupt the circulation. The $\frac{1}{12}$ gr. of theine, dissolved in 10 minims of water, was then injected under the skin of the calf of the right leg. In four minutes both of the posterior extremities were partially paralysed.

. . . .

Six grains of theine, dissolved in 2 drachms of water, were injected under the skin over the back of a healthy white rabbit, weighing 2 pounds 3 ounces. Almost immediately afterwards the ears were observed to become paler than before, then suddenly they appeared of a bright red colour, all the vessels being enlarged and congested. After remaining in this condition for half a minute they again became paler and anœmic. These sudden changes from extreme pallor to intense congestion alternated for about five minutes, each stage being about a quarter of a minute in length, after which time the ears became permanently red, hot, and congested. The animal then became restless and somewhat excited, but not hyperæsthetic, and it trembled slightly. When its toe or ear was pinched, it struggled. The force of the heart's pulsation was stronger, and the rapidity of the beats, as well as the respiratory acts, quicker than before. Pupils were unaffected. Three minutes later the hind legs struggled slightly, and they seemed to have lost power. Two minutes after, all four extremities were considerably weaker, and the rabbit was unable to stand upright, but lay flat on its belly, with all its limbs stretched out on the table. When its toe was pinched it did not struggle so much as formerly, still it pulled away its leg and attempted to crawl along, which it did in a shaky and laboured manner. The breathing was laboured and slow, the heart's pulsations were feeble, and the animal trembled. The ears were still intensely hot to the touch and congested. . . . . .

For twenty minutes the animal lay in this prostrate condition, breathing in a laboured manner, when it suddenly took a tetanic spasm, with slight episthotonos, which lasted for about a quarter of a minute . . . .

. For the next seven minutes the animal took tetanic spasms at intervals, occurring spontaneously, and not brought on by pinching or other external irritations.

Evidence of sensibility had disappeared from all parts of the body except the head, where it seemed to be normal.

The eyelids winked when the eyeballs were touched and even when the hands were clapped before them. When any portion of the face was touched its muscles contracted. The animal, although completely paralysed in its limbs, looked intelligent, as if sensation was unaffected. Ten minutes later the pupils were considerably contracted, the breathing slow and irregular, and the heart-beats not palpable. It died after a tetanic spasm. . . .

The animal never seemed to lose its intelligence. It was watchful, followed every motion of the experimenter, although it was unable to make any movement.

. . . .

Six grains of theine, dissolved in 1½ drachms of water, were injected under the skin over the back of a healthy cat, weighing four pounds one ounce. In ten minutes the animal became very angry and irritable. Fifteen minutes later this excitement had increased; the animal had a watchful, anxious appearance, prowled about, and when touched with a stick, bit at it and growled. If any noise or motion was made, it put up its back and made a hissing noise. The legs appeared weakened, and although it could still walk about, it preferred sitting in a corner of the room. Its mouth and tongue were very red, and there was an abundant secretion of saliva, which constantly trickled out of its mouth. The cat defæcated and micturated several times. Forty minutes later it continued in much the same condition. Salivation was profuse. Animal suffered from tenesmus, and it had a constant straining from the bowel of a clear fluid like mucus. The limbs, especially the posterior ones, were much weakened, but the animal could still run with difficulty. It could not jump, it made attempts to do so over a bench about two feet high, but failed. The breathing was laboured and irregular. The redness of the tongue and mouth as well as the excessive irritability of the animal had disappeared. It was quiet, lay in a corner, stupid and drowsy. It drank freely of water. Twenty minutes later it was prostrate and lay on its side, its limbs quite helpless. It paid no attention to a pinch of the toe or a blow on the tail with a stick. It seemed however to be intelligent, as its eyes watched every movement of the observer, and when the hands were clapped before its face it growled. The salivation and discharge from the bowels were excessive. Pupils were contracted, and the breathing was laboured. Five minutes later the cat took a series of tetanic spasms, and shortly afterwards died.

. . . .

A healthy white rabbit, weighing 2 lbs. 2 ozs., was carefully fastened down on its belly, an incision was made through the skin along the upper part of the spine, about two inches in length, and the vertebral column exposed. By means of bone forceps and scissors, portions of the vertebræ were removed so as to expose a piece of the spinal cord about a quarter of an inch in length. On touching the posterior column with the point of a blunt needle, the animal *struggled violently* and uttered *loud cries.* Twelve grains of theine, dissolved in two drachms of water, were then injected under the skin of the belly. In ten minutes the symptoms, already described in preceding experiments, commenced,—congestion of the ears, &c. On pinching the toe, the animal did not appear to feel it. On touching with the point of a blunt needle the posterior columns of the cord, the animal struggled, but not nearly so violent as before, and it did not cry out. When the anterior columns were touched, there were violent convulsions of the body. Five minutes later the animal was completely paralysed in all its limbs, and presented all the usual symptoms of prostration. A fresh portion of the cord was exposed by cutting away some of the vertebræ below the original wound. On touching as before the posterior columns, the rabbit only quivered slightly. On touching the anterior columns, marked muscular contractions of the limbs followed. The animal was shortly afterwards killed, and similar phenomena were observed after death as have been already described. . . . . .

These and other experiments have frequently been repeated with various modifications. . . . .

The research, however, is in its infancy; and this contribution, I trust, may be looked upon as a stepping-stone to further inquiry. — *Dr. Alexander Bennett, Edinburgh Medical Journal*, 1873–4, pp. 323–34.

As regards the physiological action of caffeine he coincides with previous experiments in considering that it causes increased reflex excitability and tetanus, the action resembling that of strychnia. If, however, one sciatic nerve be divided before the poisoning, that limb is not convulsed; hence it acts on the nerve centres. A frog is tetanised by the subcutaneous injection of a quantity not exceeding 0·005 of a gramme. 0·120 of a gramme injected into the jugular of a rabbit tetanises it, and a cat or dog is tetanised by 0·2 of a gramme. It is remarkable that by maintaining artificial respiration for some time the symptoms of tetanus entirely disappear. Its action on the heart of mammals is that it causes acceleration of the beats, with diminution of the blood-pressure; this last effect he attributes to the poison paralysing the ganglionic nerves of the heart.—*Lancet*, No. 2,551, p. 92.

Dr. Foster, having received a small quantity of the alcoholic tincture and glycerine solution of the alcoholic extract of Jaborandi, placed the drug in my hands, and requested me to observe its physiological action. I have been able to make some observations, which are confessedly very incomplete; but I am induced to publish them, since they seem to have some interest, and because I shall be quite unable to resume them until after the close of the term.

1. Effects on the general nervous system.—Injected beneath the skin of the frog, Jaborandi causes tetanic convulsions not unlike those of strychnia. These continue when the brain has been removed, but do not appear after destruction of the spinal cord. [Several other experiments are described by Mr. Langley.] At page 543–4 of the same journal may be read a report of the effects of this drug on man, by a medical practitioner, who says, "We have carefully watched the effects of the Jaborandi on the circulation, and always find that it increases the frequency of the pulse, and, except when the pulse is frequent from fever, we have never seen this drug lessen the frequency of the beats. Mr. Langley finds that Jaborandi reduces the frequency of the heart's action in animals; hence we must conclude that, in this respect, it affects man differently from animals."—*British Medical Journal*, No. 738, p. 241; and No. 747, pp. 543–4. [*See also* Hurley, p. 20; Marcet, Thorowgood, and Lanat, p. 25; Yeo, p. 38; and Reynolds and Moore, p. 39.]

[The following was a public exhibition :—]

Dr. Sanderson then exhibited a dog, into the abdominal cavity of which six drops of a pyæmic transudation liquid had been injected three hours before. The animal was in a state of profund collapse, accompanied with vomiting, purging, and cramps of the extremities. Shortly afterwards the animal was killed and the abdominal cavity opened.

The peritoneum contained liquid slightly stained with blood, which, on microscopical examination, was found to be crowded with bacteria. The intestines were distended with a frothy liquid, which possessed none of the characters of the natural contents which had been found in other cases to be charged with shed epithelium. The internal surface of the whole of the alimentary canal from the stomach downwards was intensely injected and presented appearances which (as had been found by more careful investigation in previous cases) were due to the separation of the epithelium from the surface of the mucous membrane, and the infiltration of that tissue with liquid.

The material which produced these results was obtained as follows:—Pus from a pyæmic abscess of spontaneous, *i.e.*, accidental origin, was introduced into the peritoneal cavity of a guinea-pig and allowed to remain there for two days. It was then withdrawn from the guinea-pig, and some of it at once injected in the peritoneum of a dog. The dog was affected in exactly the same way as the animal exhibited to the Society. The remainder of the liquid was kept for five weeks in hermetically sealed tubes, after which six drops were injected into the peritoneum of a guinea-pig; this showed its action to have become relatively feeble. After two days (the day before the meeting) the transudation liquid produced was tested with a third guinea-pig and found to be extremely active. On the afternoon of the meeting it was injected into the peritoneum of the dog exhibited.

. . . .

After the experiment Dr. Crisp said he differed from Dr. Sanderson in several of his conclusions. There was a great difference between tubercle in man and that in the lower animals; he had shown long ago that in monkeys and other animals no bleeding occurred from the lungs, that cavities were comparatively rare, that the liver and spleen, rarely affected with tubercle in man, were frequently so in the lower animals, and that in other particulars there were important differences. He (Dr. Crisp), as shown in their "Transactions," had inoculated guinea-pigs with pure pus from a whitlow on his own finger, and had produced tubercle, but in many respects it differed from tubercle in the human subject, although microscopically it was the same. He had also performed numerous inoculations in birds and in other animals, the results of which led him to the same conclusion. It was also important to bear in mind that there was a wide distinction between diseases of the lower animals and those affecting the human subject.

. . . .

What we wanted were experiments to ascertain whether by the use of chemical agents we could render this poison innocuous, whether by any external application we could prevent the occurrence of pyæmia. Again as regards *bacteria* being the cause of pyæmia, he entirely differed from Dr. Sanderson. *Bacteria* were found in numerous diseases of the lower animals, as had been fully shown by the French pathologists, and they were probably the effects and not the cause of the disease, as he (Dr. Crisp) had long since endeavoured to show. He was the first in this country to describe splenic apoplexy, and to point out its deleterious effects upon man and other animals. Experiments had been made by French pathologists, who showed that after the inoculation of rabbits with the blood of animals dying of this disease, that *bacteria* were found in the blood after a certain time, and that death took place at a given period. Dr. Sanderson's experiments appeared to him to have no important bearing upon pyæmia, the irritating matter he used acted more like a poison, such as prussic acid or arsenic, and killed nearly in a definite term, as others had shown.

. . . .

Mr. Hulke asked Dr. Sanderson if he had not confounded pyæmia and septicæmia. It seemed to him that the dog suffered from the latter, and not from pyæmia. If perfectly filtered pus were injected into an animal, the ordinary symptoms of pyæmia were produced, and the animal recovered; but if the pus were unfiltered, these symptoms were produced plus others, such as multiple abscesses, constituting septicæmia. Any putrescent fluid, animal or vegetable, would produce the same result.

. . . .

Dr. Murchison had often had the opportunity of examining the bodies of patients who had died of pyæmia following typhus fever, in which there were no ulcerated surfaces, no bed-sores, and no open wounds whatever, and yet in these pus had been deposited in the joints, under the skin, and sometimes in the internal organs. Everyone who had observed epidemics of typhus fever must have seen that pyæmia followed many cases, and that when one case had occurred in an hospital there were many.—*The Doctor*, 1872, p 132–3. [*See also* pp. 24 and 39.]

The following experiments will show however that all these substances when introduced directly into the blood, give rise to analogous reactions, or are followed by the same series of physiological phenomena, the only difference in them being in the quantity of the different salts required to produce these reactions.

In the following experiments the tubes by which the substances were injected directly into the blood-vessels being connected either with the jugular vein or the axillary artery, hæmadynamometer, when used, was connected with the femoral artery. The pressure is given in inches of mercury. In order to ascertain the general symptoms the animal was left at liberty, the substance being injected through a tube inserted into the jugular vein.

Salts of Magnesia.

Experiment 1.—The animal was a strong healthy dog weighing about 18 lbs., six grains of sulphate of magnesia dissolved in half an ounce of warm water was introduced into the jugular vein.

In 10 seconds the pulsations of the heart were quickened.

In five minutes the action of the heart and the oscillations were the same as before the injection.

Injected 16 grains; in seven seconds the respiration was affected, being deeper, in 10 seconds the heart was affected as before.

In 45 seconds after the injection the animal appeared to be uneasy, respiration more laboured.

After five minutes injected 25 grains, in seven seconds the respiration deeper. In 30 seconds partial spasmodic contraction of muscles . . . . .
heart's action quick, oscillation slight. 60 grains in 3 oz. of water arrested the action of the heart in eight seconds.

. . . .

Only one or two respiratory movements took place after the arrest of the heart's action.

. . . .

Experiment 2.—The animal was a healthy dog weighing 16 pounds. A tube was inserted into the right axillary artery, the point directed towards the aorta, the pressure was taken in the femoral; 16 grains of sulphate of magnesia was injected into the axillary artery. Violent struggles commencing immediately after the injection prevented the direct effect on the pressure in the arteries being observed. One minute, animal quiet, pressure one inch lower, oscillation not so great. In five minutes all effects of injection appeared to have passed, except that the pressure in the arteries was rather lower.

Injected 30 grains, apparently *considerable pain*, and in 40 seconds a general spasmodic contraction of the muscles; this soon disappeared, and the pressure on the arteries was rather lower.

The animal after a few minutes appeared not affected.

Sixty grains injected into the artery arrested the respiratory movements, in seven seconds there was a state of general tonic spasm, and in a minute and a half the animal was dead.

. . . .

Experiment 3.—Dog weighed 10 lbs., not confined; eight grains of the salt was injected into the jugular; 10 seconds, slight dyspnœa; 12 seconds, animal fell down as if suddenly paralysed. It got up almost immediately and walked about two seconds vomiting. After this the animal seemed not at all affected.

Fourteen grains injected; 12 seconds, animal fell on its side, legs extended, no spasm; the legs remained in any position they were placed; no expression of pain, although the animal was perfectly sensible, respiration regular.

After remaining on its side almost motionless for 10 minutes, the animal rose and walked about, its movements were unsteady. 35 grains arrested the action of the heart. Animal fell in 12 seconds, in 30 seconds respiratory movements arrested, animal dead. . . .

Salts of Zinc.

Page 203. Experiment 4.—The animal was a strong healthy dog weighing 15 lbs. A solution containing three grains of sulphate of zinc was injected into the jugular; in 10 seconds the respiration was affected, and the action of the heart rendered slower; in 15 seconds the pressure in the arteries began to fall, and in 35 seconds it had diminished. . . . . . .
after five minutes the pressure was still down . . .
oscillation slight. . . . .

Injection six grains; no apparent immediate effect on the action of the heart, but in 15 seconds the pressure in the arteries began to fall, and in 30 seconds it was only equal to two inches, the respiration was irregular; one minute, efforts to vomit; two minutes, heart stopped, but respiratory movements and efforts to vomit continued one minute after the pulsations of the heart had apparently ceased, at least the pressure in the arteries had sunk to zero.

. . . .

Experiment 5.—A solution containing 6 grs. of sulphate of zinc was injected into the axillary artery of a dog weighing 10 lbs. There was immediate expression of pain and partial spasm; 45 seconds, the animal quiet, the pressure in the arteries was about one inch lower, oscillation not so great; two minutes, vomiting.

Injected 15 grains; five seconds, respiration suspended, spasm, retraction of head; animal died in two minutes. The heart continued beating three minutes after respiration was suspended, and after the thorax was opened.

. . . .

Experiment 6.—Dog weighing 8 lbs., it was not confined. Inject three grains of sulphate of zinc into the jugular; no marked effect. Inject six grains, 12 seconds after the injection the animal fell down and lay on its side perfectly powerless, no spasm; 45 seconds, efforts to vomit; urine and fæces passed; the animal lay for some minutes perfectly still, the respiratory movements became slow and weak, so that its pulsation could not be felt through the chest, but pulsation in the femoral; sensibility unimpaired; no expression of pain. After 10 seconds inject three grains; 15 seconds, some slight movements, as if the animal was uneasy; respiration slower, ceased at two minutes three seconds; no convulsions; on opening the thorax the heart was found pulsating slowly but rhythmically.

. . . .

Experiment 7.—A strong solution of the salt was injected into the jugular of a dog weighing 12 pounds; in 7″ the pressure in the arteries began to sink; in about 45″ was at zero; no pulsation of the heart after 7″. Animal dead 1′ 30.

. . . .

Page 204, Experiment 8.—Salts of Manga.—Dog weighed 11 pounds. Injected 5 grains of sulphate of manga.; 10′ heart's action affected, oscillation less; no sign of pain; pressure diminished 1 in.; 1′ 30″ vomiting.

Inject 10 grains; heart stopped 10″; animal died 1′ 45″. On opening the thorax heart still.

. . . .

Experiment 9.—Dog 9 pounds, not confined. Inject 3 grains into the jugular. 20″ animal fell on its side. Again rose and walked about, lay down again in 2′; lay perfectly still in the same position for 10 minutes, although it could walk when roused. It remained five minutes without moving, the head and thorax resting on the ground, the back part of the body supported by the hind legs; there appeared a total absence of volition; no expression of pain, no convulsions. Inject 4 grains; animal dead in 2′.

. . . .

Experiment 10.—Salts of Cobalt.—Dog weighed 13 pounds. Inject 5 grains sulphate cobalt. 12″ heart affected; 15″ respiration rather deeper; the pressure diminished; at 3′ it had fallen ·3 in.; efforts to vomit. After 10 minutes the animal appeared not to suffer. Inject 10 grains; blood in tubes coagulated, but in 3′ the pressure was 2·5′ in., it having been before the first injection 8·9 in.; respiration slow, heart's action weak.

Inject 10 grains; in 10″ heart stopped; respiration continued 2′ longer. On opening the thorax the heart was still irritable but did not contract rhythmically.

. . . .

Experiment 11.—Dog 15 pounds, unconfined; 4 grains sulphate of cobalt was injected into the jugular; 45″ the animal lay on its side; respiration rather slower; 3′ vomiting. At the end of half an hour the animal still disliked moving.

. . . .

Inject 10 grains; prostration complete; animal lies like a dead mass; respiration slow, regular action of heart weak. After 10′ it could stand. Inject 15 grains; 10′ the animal fell on his side, head drawn back, struggled a little; respiration stopped 2′. On opening the thorax the heart was found motionless.

. . . .

Experiment 12.—Salts of Nickel.—Dog, weight 20 pounds, pressure 5 to 7 in. Inject into jugular 3 grains of sulphate of nickel; 10″ heart affected, quicker, oscillations less; 45″ pressure 4·2 in.; 2′ efforts to vomit.

Inject 6 grains; 12′ heart quicker, respiration deeper. 2 pressure 3 in.; respiration quiet and slow; pulsations 58. Animal appears not to suffer; lies quiet.

8′ inject 9 grains; heart stopped in 14″; respiration continued 2·30. On opening the thorax heart moved slightly.

. . . .

Experiment 13.—Dog weighed 12 pounds, not confined; 3 grains of sulphate of nickel was injected into the jugular; no immediate effect; 3′ vomiting; 7′ inject 6 grains; animal fell down; 30″ no expression of pain, no convulsion; breathing regular, slow; sensibility unchanged; remained in this state for some time without the slightest voluntary movement.

Inject 10 grains; heart stopped; animal dead in 2′.

. . . .

Experiment 14.—Salts of Cadmium.—Dog weighed 30 pounds, unconfined; 1 grain of sulphate of cadmium in 2 oz. of water was injected into the jugular; no appreciable symptoms. Inject 2 grains; 30′ animal appeared dull; 1′ 30″ vomiting; 5′ inject 3 grains; 45″ vomiting renewed; 4′ animal fell down, lay like a dead mass; respiration regular but slow; no symptoms of pain. On being placed on its feet it would stand for a few seconds, but then gradually sunk down. Inject 6 grains; respiration stopped in 1′ 45″; on opening the thorax heart still.

. . . .

Experiment 15.—Salts of Copper.—Dog, weight 15 pounds; inject 3 grains sulphate of copper into the jugular; 12′ the action of the heart affected . .

2′ heart slower. Inject 6 grains, 10′ heart fluttering for a few seconds; 45″ pulsations slower, from 84 to 55; respiration slower; pressure in arteries diminished 2 in.; efforts to vomit. Inject 15 grains; 12″ heart stopped; respiration continued 30″, then arrested for 45″, then recommenced and continued slowly for 45″, the heart apparently beating feebly, although no effect was produced on the pressure in the arteries. 3′ animal dead; on opening the thorax the heart was still.

. . . .

Experiment 16.—Dog, weight 18 pounds; a solution containing 2 grains sulphate of copper was injected into the axillary artery; 10″ general tonic spasm, which lasted 40″; respiration then recommenced and continued about 1′; the pressure in the arteries fell gradually, the heart being stopped by asphyxia.

On making an incision into the parietes of the thorax 3′ after the animal had been to all appearance dead, a full inspiratory movement of the parietes of the thorax and of the diaphragm took place.

. . . .

Experiment 17.—Dog weighed 12 pounds, not confined; inject 3 grains sulphate of copper into the jugular; 35″ the animal seemed uneasy, but no expression of pain; respiration rather deeper; 2′ vomiting; 5′ inject 4 grains; 12″ respiration deeper, more laboured; 20″ animal lay down, stretched out its legs and cried; no convulsions, sensibility unimpaired; 2′ rolled over on its back; 3′ respiration short and quick; 4′ efforts to vomit, and the animal rose for a short time, but soon fell again; 6′ inject 4 grains; 12′ respiration deeper; 45″ respiration stopped; no convulsive movements, but perfectly still. 1′ 30″ respiration again began, and continued at intervals for 1′ 30″; eyes closed on irritating conjunctiva 2′ after injection. On opening the thorax the ventricles were found contracting slightly.—*Journal of Anatomy and Physiology*, 1870, p. 201 and following pages.

Rabbits.—The sub-cutaneous injection of three grains of bromal hydrate produces the following effects on a rabbit of three or four pounds weight. During the first three or four minutes nothing is observed. The animal then becomes restless, and moves about quickly, rubs its nose with its fore feet, the vessels in the ear become dilated and full of blood, the pupil contracts quickly, but at an equal rate, from its original diameter before injection of 6 M M, or 7 M M to 1 M M, that is, to its maximum X of contraction. In one or two minutes more, the blood vessels of the conjunctiva, more especially on the inner surface of the lids, are injected, and there is great excess of lachrymal secretion, the mucous membrane of the mouth and nostrils also becomes red, and a profuse secretion pours from the mouth. The amount of secretion is often so great as to endanger the life of the animal from suffocation, and it may be collected easily in a watch-glass.

. . . .

The respirations become gradually more rapid until they are nearly double their normal amount. The cardiac pulsations are in the first instance diminished in number, afterwards they become more rapid, and they may become double the normal number. Towards the period of death they are much reduced both in number and in force. The animal then lies flat on its abdomen and chest, with the fore and hind limbs in spread-eagle fashion. There is paralysis of both fore and hind extremities. There is no hyperæsthesia so far as can be determined by pinching, or by weak induced currents. In a few minutes more the head sinks on the table, the respirations become slower and more laboured, the heart beats less rapidly and more feebly, muscular twitchings are seen, and after a few clonic spasms the animal dies, frequently in a state of episthotonos. This is the general picture of the action of a minimum lethal dose which kills in from one to two hours. With a larger dose the symptoms are more intense. The animal becomes much excited, the pupil contracts with great rapidity to its smallest diameter, and after screaming for a few seconds, as if in great pain, it dies in convulsions.

With a smaller dose the phenomena just noticed follow consecutively, but the symptoms are less acute, and after a period of stupor the rabbit may recover.

. . . .

A dose of five grains produces great distress within four or five minutes. The animal is excited and appears to suffer acute pain. This condition is coincident in time with the contraction of the pupil and the dilatation of the blood-vessels. During the first four or five minutes the animal is quite able to run or leap, but at the end of that period there is staggering, and very soon the power of voluntary movement is lost. . . . . .

When the chord has been involved several convulsions ensue. During the paralytic condition the nerves are still sensitive to very weak induced currents. The sensibility and conducting power appear to be intact. The action is therefore on the cerebral and spinal centres, and not on the peripheral terminations of the nerves.—*Dr. McKendrick*, Physiological Laboratory, University of Edinburgh. —*Edinburgh Medical Journal*, July 1874–5, p. 2.

Note.—Since the above was written, I have experimented by injecting acetic acid into the pleural sac of the horse. The experiment was made more for the purpose of determining the rapidity with which false membranes may form in the chest in pleurisy, and the results are as follows:—

Before the experiment the temperature was 96·4°, pulse 40, and respirations 12. The acid was injected at 10. 35 a.m. At 10. 50 the animal was restless, with a pulse of 48. At 11. 15 there was observed twitching of the superficial muscles of the right side, with slight gastric tympany, and a pulse of 52. At 12 the temperature was 101·4, and now and there was a slight abdominal breathing, with a visible line of demarcation, while the pulse was 54 and hard. The animal remained in this condition for some time, and at 8 p.m. it was found that the pulse had risen to 105°.

On the following day (morning) those symptoms had passed off. The animal was slaughtered forty-eight hours after the injection. A post-mortem having been made, there were found bands of lymph, partly organised on the pleural surface, hydrops pericardii, the quantity of the serum taken from the pericardium being about a quart. The pericardium and endocardium were both highly injected—*"The Principles and Practice of Veterinary Medicine," by William Williams, M.R.C.V.S., F.R.S.E., &c.*, p. 336.

To ascertain this they tested the first material ejected in vomiting in a number of dogs into whose veins tartar-emetic had been injected, and found that it always contained some of the antimonial salt. The fact that efforts to vomit may still occur after the stomach has been excised they do not regard as at all opposed to their view, since the salt may act on the peripheric extremities of nerves supplying the œsophagus or intestine, which also may have the power of inducing vomiting reflectorially.—*Lancet*, No. 2,561, p. 463.

To prevent coagulation of the blood, Dr. Braxton Hicks has recommended the addition of a small quantity of phosphate of soda (Guy's Hospital Reports, 1868, p. 14), and Dr. Richardson minute quantities of ammonia. Even in very small proportions, the ammonia not only prevents or retards coagulation, but in transfusion it acts as a stimulant to the system. Great care is required in using it. Injected into the veins of a dog, insufficiently diluted, it produced convulsions.—*Dr. Madge, British Medical Journal*, No. 680, p. 43.

The experiments made at Norwich by Dr. Magnan were similar to the following, described by himself several years ago:—The dangers of prolonged indulgence in absinthe drinking have been pointed out by many writers, and recently experiments have been made to ascertain the nature of the poisonous action of this substance. Drs. Magnan and Bouchereau add some facts to what is already known (Comptes Rendus, 5 Avril 1869); they administered the poison to dogs, cats, rabbits, and guinea-pigs, and found that convulsions of an epileptic character were quickly produced. The convulsions, they further show, are caused by some component part of the Artemisia Absinthium, and not by the alcohol in which it is dissolved. —*Journal of Anatomy and Physiology*, 1870, p. 313.

In order to compare the capability of resistance in inflamed parts with that in the normal condition, v. W. produced inflammation of the mesentery of the frog by means of cantharides. The animal was injected next day, and always at the same time a sound one for comparison. The injected matter consisted of water, soluble Berlin blue, and gelatine; and the injection was made by means of Hering's apparatus with constant pressure.

The result of 70 experiments was, that as well in normal as in inflamed mesentery, the injected mass passed through the walls of the vessels. . . . .

Similar results were obtained by another series of experiments, where the frog pumped the mass into the vessels by the action of its own heart.—*Journal of Anatomy and Physiology*, February 1875, p. 228.

Vulpian exposed the heart of a curarised dog, and in order to diminish the rapidity of its movements, a quantity of infusion of digitalis was injected into the femoral vein.—*Journal of Anatomy and Physiology*, February 1875, p. 230.

The animals used for experiment were the dog, the rabbit, the sheep, and the frog. Into the dog were transfused the blood of the sheep, of the cat, of the guinea-pig, of man, the frog, the calf and the pigeon; into the rabbit, that of the hare, sheep, calf, and man; and the blood of man into the sheep. A special series of experiments was made with frogs, which were injected with the blood of the dog, rabbit, sheep, man, calf, guinea-pig, pigeon, and pike. The blood of the rana temporaria was also injected into the rana esculenta. The results of these painful experiments are given thus:—

"In many kinds of blood also, when mixed with the " blood of the serum of other species, the blood corpuscles, " are seen to run together into masses; and these masses, " when transfusion is made into the venous system, may " block up the pulmonary capillaries and give rise to very " formidable symptoms." Dr. Laudois remarks that numerous experiments with various modifications are required for the solution of the questions that await an answer.—*British Medical Journal*, No. 687, pp. 280 and 281.

Dr. Guérin has repeated an experiment which was performed by Blundell and others long ago, a sort of double transfusion. Two dogs are placed side by side, and the carotid artery of each animal connected by means of a tube with the jugular vein of the other. In this way they obtain a common circulation, after the fashion of the Siamese twins. Although a most interesting experiment, this can only be regarded as one of the curiosities of transfusion.—*British Medical Journal*, No. 680, p. 44.

The Poison of some Indian Venomous Snakes administered to Dogs, &c. by Drs. Brunton and Fayer.

The general symptoms are depression, faintness, hurried respiration and exhaustion, lethargy, nausea and vomiting. In guinea-pigs and rabbits peculiar twitching movements occur which seem to represent vomiting in them, and occasionally in fact, guinea-pigs do vomit. Dogs vomit, are salivated, and present an appearance as if the hair had all been rubbed the wrong way, "staring." As the poisoning proceeds paralysis appears, sometimes affecting the hind legs first and seeming to creep up the body, and sometimes affecting the whole animal nearly at the same time. There is a loss of co-ordinating power of the muscles of locomotion.

Hæmorrhage, relaxation of the sphincters, and involuntary evacuations, not unfrequently of a sanguineous or muco-sanguineous character, often precede death, and it is generally accompanied by convulsions.

In fowls the appearance is one of extreme drowsiness; the head falls forwards, rests on the beak, and gradually the bird, no longer able to support itself, rolls over on its side. There are frequent startings, as if of sudden awaking from the drowsy state. . . . .

Experiment 1.—1.30. Three drops of this, diluted with water, were injected into the flank of a small dog. Immediately after the injection the corresponding leg was drawn up partially paralyzed.

1.32. He walks less steadily. Tail rigidly held out.

1.35. Is restless and whining. Walks about and then sits down again. Walks unsteadily.

1.45. There are distinct muscular twitches in the shoulder. General tremor.

1.47. There are twitching movements of the back.

2.8. Has been standing perfectly still. Is now pawing and licking his lips. Vomits.

2.10. Vomits again, but licks up part of what he had ejected.

2.22. Has been continually vomiting. The ejection consisted at first of food, afterwards of tenacious mucus. He now lies down apparently exhausted. He is still trying to vomit but can bring nothing up. He tries to rise but cannot. Convulsive struggles occur.

2.25. Breathing has ceased, but the cornea is still sensitive. Convulsive attempts to vomit.

2.27. Cornea insensible. Heart is still beating strongly. Death soon followed.

Experiment 2. A young rabbit weighing 900 grammes was used. An incision had been previously made through the skin of the neck, and the wound again sewn up, but the animal was otherwise uninjured. Two drops of cobra poison weighing 12 centigrammes were diluted with 1 cubic centimetre of water.

At 4.6. The diluted poison was injected under the skin of the left hip.

4.7. Washed out the watch glass in which the poison had been placed with water, and injected it under the skin of the back. The animal sat quiet after the injection occasionally licking its fore paws.

8′ 30″. Respiration seems hurried. The rabbit occasionally makes a jerking motion with its hind feet.

10′. Has been restless, running about occasionally licking its fore feet.

13′ 30″. Still very restless and when held makes convulsive efforts to get away. Ears are much congested.

17′. The animal is now quiet, its ears are no longer congested.

About 20′. Quiet with occasional starts. Disinclined to move but can walk quite well.

25′. Movements seem difficult and hind legs seem weak when it tries to walk.

26′. Paralysis of hind feet is increasing.

26′ 15″. The rabbit lays its head down on the table.

28′. When laid on its side it merely makes a few slight movements with its fore paws, and then lies still. The eyes remain in a half closed condition and have done so for some time. When the cornea is touched the head gives a jerk, but the eyelids move very little. Respiration slow and laboured.

4.30. The chin is twitched inwards, the sternum once or twice, the hind feet at the same time being twitched backwards. The eyes open widely. Slight convulsive extension of limbs.

4.31. Respiration has stopped, cornea is insensible; thorax opened immediately. There were large extravasations of blood under the skin of abdomen and thorax, and under the skin of the left hip. Heart beating vigourously.

The muscles contracted on direct irritation. The foot twitched when the sciatic nerve was exposed and irritated by an interrupted current. The peristaltic movements of the intestine were active after the abdomen was opened.

Experiment 3. Dissolved 5 milligrammes of dried cobra poison which had collected round the stopper of the bottle containing it in 1½ cubic centimetre of water, and injected it under the skin of the left hip of a guinea-pig weighing 790 grammes.

In three-quarters of a minute after the injection the animal became restless and uneasy and began to cry.

1½′. It began to give little starts.

3¼′. The starting motions became greater, the hind quarters of the animal being jerked upwards and the chin drawn in towards the body; continues to cry.

4¼′. Passes water.

7′. Less restless.

15′. Washed out the watch glass in which the cobra poison had been placed with about half a cubic centimetre of water, and injected it as before. Immediately afterwards the restlessness increased.

24′. Seems to be trying to vomit.

27′. It cannot walk rightly.

28′. The hind legs are paralyzed and spread out laterally from beneath it.

29′. Respiration very slow and deep. The animal lies quiet, but convulsive twitches of the limb follow almost every respiration. Respiration 8 in half a minute.

30′. Cornea insensible. Respiration has ceased. Post mortem examination made immediately. The left venticle was much dilated, the right ventricle empty. There were two beats of the left auricle for every one of the ventricle, and the ventricular beat was weak and imperfect.

Experiment 4.—Dissolved 1 centigramme of a substance like gum, and labelled "alcoholic extract of cobra poison" in one cubic centimetre of water. It dissolved easily and formed a somewhat opalescent solution.

Injected about one-third of this (equal to 3½ milligrammes of the dried extract) under the skin of the thigh of a rabbit weighing about a kilogramme. Four minutes after the injection there was no apparent effect; so a similar quantity was again injected, making the total amount received by the rabbit 7 milligrammes of extract; five and a half minutes after the first injection the animal became very restless.

7′. Respiration rapid. The vessels of the ears were noticed to be much injected. On continuing to observe them the injection disappeared, and then returned again. The alternate filling and emptying of the vessels was much more perceptible than in the normal condition. The rabbit sits quietly, but every now and then gives a start.

22′. The condition of the ears has continued the same. The eyes are becoming half shut and the eyeballs turned up.

The animal now begins to tremble. The head is laid down on the table and then raised again; this is succeeded by a nodding motion of the head. The head is next laid down on the table. Respirations twenty-two in fifteen seconds.

24′. The animal has sunk down on its face and paws as if its fore legs would no longer support it. The hind legs, however, still support the posterior part of the body. Respirations eleven in ten seconds. It seems to be trying in vain to raise its head.

26′. Respirations eight in ten seconds. Convulsions. The cornea is sensitive. The rabbit is now lying on its side. Respirations five in fifteen seconds. Pulse twelve in eighteen seconds.

31′. Cornea is nearly but not quite insensible. The eyeball is protruding.

About 31½′. Respiration has stopped. The heart is still beating vigorously.

32′. Cornea insensible. The animal opened immediately. The heart was beating vigorously, twenty-one beats in ten seconds.

An attempt was made to insert electrodes into the spinal cord and pass uninterrupted current through them. No effect followed; but it is not certain that they were well in the cord. Irritation of the nerves going to the hind legs by uninterrupted current had but a slight effect. Direct irritation of the muscles caused them to contract. After the irritation was discontinued, a fibrillary twitching was observed in one of the extensions of the thigh.

42′. Heart still feebly pulsating. Irritation of the brachial, sciatic, and crural nerves has very little effect.

45′. Heart still feebly pulsating.

Experiment 5.—Two drops of cobra poison were injected under the skin of the thigh of a guinea-pig. One or two minutes after the injection the legs of the animal began to twitch. It was then covered with a glass bell jar.

6′. After injection. The legs are again twitching. This is a peculiar motion of the hind legs, in which they seem to make an abortive attempt to kick involuntarily.

7′. Respirations are deeper than usual.

9′. Legs again twitching.

10′. The animal is restless, and moves round and round inside the bell jar. Grunts occasionally, and grinds its teeth. The hind quarters are twitched upwards and the nose is drawn in towards the chin at the same time.

13′. Bites at the spot where the injection was made and passes water.

22′. It can no longer walk.

23′. It has sunk down and lies flat on the table, leaning rather to one side. Respirations are deep. There are occasional twitches of the legs.

25′. Cornea is sensitive. Occasional convulsive stretches.

27′. Cornea almost insensible. Respiratory movement of nostrils continues.

28′. Cornea completely insensible. Post mortem examination made immediately. The muscles of the abdomen were dark coloured. Peristaltic movements of the intestines occurred when the abdominal cavity was opened. The heart was dark and slightly dilated; all its cavities were contracting though feebly. There were three beats of the auricles to each one of the ventricles. Irritation of the nerves in the pelvis caused contractions of the legs.

35′. After injection. The heart is still feebly contracting.

Experiment 6.—October 28th. Injected about a grain and a half, or two grains, of the precipitate which was thrown down from cobra poison by alcohol, into the thigh of a guinea-pig.

App. IV.

2.30. Injection made. A few minutes afterwards it passed some milky looking water and then remained perfectly quiet.

3.8½. Passed water which was quite clear.

3.33. Injected about two grains into the right femoral vein. It passed clear water almost at once.

3.35. Its nose gave a jerk inwards. Wounded leg drawn up.

3.38. Nose twitches frequently, and the animal emits a faint barking sound.

3.40. Slight tremors.

3.50. Begins to eat a piece of bread placed near it.

3.58. Still twitches.

4.8. Is still sluggish, but seems nearly well. Recovered.

Experiment 7.—October 29, 1872.—About ½ a grain of fresh but coagulated and cheese-like cobra-poison was suspended in distilled water and injected into the back of a guinea-pig weighing about a pound and a quarter.

2.23. Injection made.

2.26. The animal looks scared and is twitching. This guinea-pig is very active.

2.30. Another dose injected. The animal is twitching much. It jumped out of the deep box in which it had been placed for observation. Breathing is hurried.

2.36. It seems better. Another dose injected into the thigh.

2.45. Not much effect. Another dose injected.

2.46. Twitching continues; animal remains active. It recovered. . . . .

Snake poison probably produces its fatal or deleterious effects either by completely paralyzing the nerve centres or other portion of the nervous apparatus, and thus causing arrest of respiration, or by partially paralyzing them, and also poisoning the blood, thereby inducing pathological conditions of a secondary nature, which may according to circumstances cause the slightest or most dangerous symptoms.—*Proceedings of the Royal Society,* Vol. 21, No. 145, pp. 365–70.

An opportunity occurred to me in June last of performing some experiments with the poison of the cobra di capello or *Naja Tripudians.* A small quantity of the cobra poison in a dry state was given to me by Mr. Blackburn, formerly a pupil at Guy's Hospital. . . . . with the aid of my colleague, Dr. Pavy, the experiments were performed in his physiological laboratory. . . . . . .

Two grains thus dissolved, including the gelatinous portion, were introduced into a wound made in the side of a rabbit by Dr. Pavy, the wound penetrated into the cellular tissue beneath the skin, very little blood escaped. The edges of the wound were then sewn up. No particular symptoms manifested themselves for a quarter of an hour. Mr. K. Ashby undertook to watch the animal, and I subjoin a note of his observations.

Operation completed.

Began to show symptom of loss of power in limbs, particularly in hind legs, resting its body on the table without supporting itself on its limbs. It got up and moved when irritated. Respirations quick.

Cannot support itself on its legs

Lies over on its side. Respiration slow.

Eyelid shut lazily when the corner is touched.

Eyes insensible to the touch, six or eight slight convulsions.

Respirations, all movement ceased twenty minutes after the poison had begun to act. Chest opened five minutes afterwards. Heart still beating, and continued to beat for five minutes after the chest was opened, when it became engorged and stopped.

A middle-sized healthy dog was selected for the next experiment. The animal had been kept without food for many hours. Two grains of the poison finely powdered and mixed with a small quantity of powdered gum to give it uniform consistency, was brought to a fluid state with half an ounce of water. This was injected into the stomach of the animal by means of a catheter.

No symptoms of poisoning were at any time observed, and in the following day the dog was as well as usual, and took his food with appetite. — *Dr. Taylor, Guy's Hospital Reports,* 1873, p. 297.

About 280 experiments are recorded performed by Dr. Fayrer on dogs, cats, pigs, kids, birds, rats, horses, and several other animals, consisting of various snake bites. It is needless to add that the animals suffered much pain for periods of from one to several hours duration—in some instances 70 hours.

Nine experiments were performed on dogs, pigeons, and fowls.—*Edinburgh Medical Journal,* Vol. 14, p. 522.

Twenty-seven experiments were performed on fowls, dog, cat, frogs, and fish.—*Ibid.,* pp. 915–21.

Nineteen experiments were performed on dogs, cats, birds, pig, &c. &c.—*Ibid.,* p. 996.

Six experiments on dogs, pig, snake, and civet cat.—*Ibid.,* Vol. 15, p. 236.

Two experiments on two horses.—*Ibid.,* p. 242.

Fourteen experiments on fowls, cats, and snakes.—*Ibid.,* p. 245.

Thirteen experiments were performed on fowls, chicken, and snake.—*Ibid.,* p. 334.

Twenty-one experiments were performed on snails, fowls, dogs, chickens, and snakes.—*Ibid.,* p. 417.

Two experiments on snakes.—*Ibid.,* p. 423.

Four experiments on cock, rabbit, and dog.—*Ibid.,* p. 427.

Five experiments on dogs.—*Ibid.,* p. 428.

Two experiments on dogs.—*Ibid.,* p. 429.

Four experiments on dogs, kid, and pigeon.—*Ibid.,* p. 620.

Eleven experiments on dogs, fowls, and snake.—*Ibid.,* p. 807.

Nineteen experiments on dogs, cats, and fowl.—*Ibid.,* p. 813.

Eight experiments on dogs, kittens, and snakes.—*Ibid.,* p. 994.

Ten experiments on dog, fowl, and snake.—*Ibid.,* p. 998.

Three experiments on dog and fowls.—*Ibid.,* p. 1000.

Six experiments on dogs and fowls.—*Ibid.,* p. 1099.

Four experiments on dogs.—*Ibid.,* p. 1104.

Five experiments on dogs and fowls by the cobra poison. —*Ibid.,* p. 1106.

Six experiments on dogs and fowls by cobra poison.—*Ibid.,* Vol. 16, p. 53.

Five experiments on dogs and fowls by cobra poison.—*Ibid.,* p. 56.

Seven experiments on dogs, cats, and snake, by cobra poison and carbolic acid.—*Ibid.,* p. 57.

Four experiments on dogs and fowls by cobra poison.—*Ibid.,* p. 135.

Four experiments on dogs and fowls by cobra poison.—*Ibid.,* p. 137.

Three experiments on dogs and fowls. Cobra poison. Dr. Fayrer says:—"I have seen as much difference "between the effects produced by different daboias, or by "the same daboia on different animals of the same species, "as in those that had been bitten by the cobra; and on "the other hand similar differences in the effects of the "bites of different cobras, or of the same cobra on different "animals of the same species, as in those bitten by the "daboia."—*Ibid.,* p. 139.

Four experiments on dogs and fowls. Cobra poison.—*Ibid.,* p. 423.

Seven experiments on dogs and fowls. Cobra poison.—*Ibid.,* p. 426.

Five experiments on dogs and fowl by snake bites.—*Ibid.,* p. 430.

Six experiments on dogs and fowls by snake bites.—*Ibid.,* p. 431.

Two experiments on dogs by snake bites.—*Ibid.,* p. 434.

Five experiments. Dogs and fowls.—*Ibid.,* p. 435.

Five experiments performed on dogs and fowls by snake bites. [One of the dogs is described as "wildly excited, "whining, and licking the bitten part, which is bleeding "and swollen."]—*Ibid.,* p. 628.

Six experiments of much the same character as the above, the animals remaining in great suffering for from 2 to 70 hours.—*Ibid.,* p. 631.

The following will generally serve to describe the 280 experiments, as regards the sufferings of the animals.

No. 1. A full-grown pariah dog was bitten in the thigh by a full-grown and vigorous *cobra,* of the variety called by the snakemen kurees keauteah. Two tablespoonfulls of Mr. Otho Alexander's fluid antidote was poured down the dog's throat immediately after the bite, which was inflicted at 12.18 p.m., and the vegetable extract or paste, made into the consistency of honey with liquor ammonia, was well rubbed into the wound and over a large surface round it. . . . .

12.19 p.m., the dog limped on the bitten leg, and seemed restless and uneasy; 12.26, retching; 12.30, very restless, breathing hurried; 12.31, vomiting; 12.33, staggering, profuse defæcation; 12.34, convulsed; diarrhœa; rises, staggers, and falls over into convulsions; 12.35, violent convulsions; 12.37, perfectly paralysed, heart still beats, no respiration; 12.38, dead, in 20 minutes after the bite. . . . .

No. 5. A fowl had 20 drops of the blood of the dog, poisoned by a cobra in experiment No. 1, injected with the hypodermic syringe into each thigh at 12.42 p.m. 12.50, crouching; 12.55, crouching, feathers ruffled; 1.5, sluggish, eyes closed, drowsy; 1.30, stands with head depressed, feathers staring, eyes closed, very drowsy; 2, very drowsy, head drooping; after this the fowl slowly recovered, and on Monday 24th was quite well. The poison in this experiment must have been infinitesimal in quantity, only 40 drops of the blood of a full-grown dog poisoned by a cobra were injected. The symptoms of poison were well marked, though the bird ultimately recovered.

No. 6. A solution of one part of cobra poison to eight parts of liquor potassæ was prepared by Dr. Ewart, and of this nine drops were injected into a fowl's thigh at 12.57 p.m. There was a floculent-looking deposit caused by the mixture of the fluids. 1 a.m., drooping; 1.2, crouching; head falling over, nearly paralysed; 1.4, convulsed; 1.7, dead, in seven minutes, with all the symptoms of cobra poisoning. . . . . . .

No. 8. Twenty drops of the blood of the above fowl, removed immediately after death, injected into either thigh of a fowl at 1.10 p.m. 2.15, sluggish; 4.10, drowsy, head falls over; 4.20, no convulsions; 7.15, dead, in six hours and 15 minutes. . . . .

No. 10. A fowl was bitten in the thigh by a Bungarus cœruleus (Krait) at 1.22 p.m. 2.24, feathers staring, eyes have a fixed glaring stare; 1.25, stretches out the neck, falls over, point of beak resting on the ground; 1.26, convulsed, puncture in thigh ecchymosed and œdematous; 1.29, dead, in seven minutes. . . . .

No. 11. A cat was bitten in the thigh by a cobra (Tentuliah keauteah) at 1.46 p.m. Mr. O. Alexander's antidote and extract was administered, according to his instructions, immediately, 1.47 p.m. Pupils widely dilated; cat lies stretched out, hurried breathing; 1.51, convulsed; 1,52, paralysed, heart still beats, no respiration; 1.55, dead, in nine minutes.

This cat was on a former occasion bitten by a large Bungarus fasciatus, and showed no sign of poisoning. .

No. 12. A fowl was bitten in the thigh by a large Bungarus fasciatus at 1.44 p.m. 1.54, drooping head, falling forwards; 1,58, convulsed, cannot stand; 2 p.m., convulsive movements; there is a peculiar vocal sound as though the thorax was compressed; 2.5, convulsed; 2.10, dead, in 26 minutes. . . . .

No. 13. A young rat was bitten in the thigh by a Bungarus cœruleus at 2 p.m.; insensible immediately, dead in 30 seconds.—*Ibid*, 1870–71, p. 721.

Irritation of the roots of the pneumogastric, in Bernard's famous experiment of puncture of the fourth ventricle, has the same effect as similation of its trunk.

This experiment is performed by pushing an instrument like a bradawl through the skull and cerebellum till it reaches the olivary fasciculi in the medulla oblongata.—*Dr. Brunton, British Medical Journal*, No. 680, pp. 40 and 41.

For the experiments *non*-narcotised dogs were for the most part employed, the surface of the brain being stimulated by weak induced currents. In general, the facts already known were confirmed.

. . . .

After stimulation with quite weak currents, after movements, dependent on the stimulated centre, were manifested by the muscles, which movements often passed into general *convulsions*, but could only be produced from the points which were to be regarded as so-called centra.—*Journal of Anatomy and Physiology*, February 1875, p. 210.

The author's experiments upon rabbits confirm the statement of Riegel and Jolly that the vessels of the pia mater do not contract upon a stimulus being applied to peripheral sensory nerves. After an experiment upon a tracheotomised rabbit (to which no curare had been given) had shown that this poison had no effect on the vasto motor channels; it was tried to investigate the central circulation without trepanning, and with the exclusion of air, viz., by ophthalmoscopic examination of the retinal vessels.

The occurrence of a strong and continual flow of tears, rendered every attempt at examination fruitless.

Lastly the experiments with trepanning and the setting a piece of glass in the skull seemed to be useless, in that the action of the air caused inflammation.—*Journal of Anatomy and Physiology*, February 1875, p. 213.

Veyssiere has recently made some experiments on the localization of sensibility in the dog. The method he employed was to introduce a puncture in the cranium. The stylet was then withdrawn, and another bearing a concealed spring which could be thrust out at an angle from its extremity was pushed down the cannula, the spring projected and the requisite laceration made, the spring recovered, and the instrument withdrawn.

No. 1. The lesion was limited to the posterior part of the intraventricular portion of the corpus striatum and the anterior part of the optic thalamus on the left side. Imperfect hemiplegia and hemiancœsthesia of the right side. The hemiplegia passed off in twenty-four hours, the animal was well in three days.

. . . .

[The other four experiments are of the same character.]
—*Edinburgh Medical Journal*, January 1875, p. 659.

By means of a sharpened spoon the outer and upper portion of the anterior lobe of the hemisphere was so far removed that the parts lying immediately outside of the anterior portion of the lateral ventricle were exposed, without, however, opening the ventricle. (The anterior can be opened without injury.) The deepest part and that lying next the middle line in this prepared surface corresponds to the corpus striatum.

When the surface of the corpus striatum was stimulated electrically, it was shown —

1st. That movements of the muscles of the opposite side occurred upon the application of weak induced currents.

2nd. That the points where stimulation of the intact surface of the brain was followed by distinct groups of movements are also present on the surface of the corpus striatum.

3rd. That the opposite position of the active points is the same in the corpus striatum as in the surface of the brain.

If the deepest part of the corpus striatum is stimulated the animal opens its mouth, puts out its tongue, and draws it in again alternately.

These are the movements whose centres are pretended to be found on the convolutions of the under surface of the brain, *i.e.*, lower frontal and suprasylvian convolutions.—*Dr. Sanderson, Journal of Anatomy and Physiology*, November 1874, p. 209.

In his experiments on this subject, Afanasieff divided one or both peduncles through a hole in the temporal bone. In consequence of the transitory irritation which the section produced the animal immediately afterwards drew itself together, the head was inclined to that side on which the peduncle had been divided, the pupils became contracted, especially on that side, and the arteries of the ears also contracted, but their contraction was more marked in the ear of the opposite side. In six seconds after the operation all the above-mentioned effects were succeeded by their opposites. The irritation also produced increased flow of tears and saliva, and twitchings of the extremities on the side opposite the section, all of which lasted for half an hour. Section of one peduncle between the pons and the tuber cinereum produced paralysis of the muscles of the extremities on the opposite side, and of those of the back and neck on the same side. The amount of paralysis increased with time. . . . . .
In two or three weeks it was again able to run straight forward.—*Journal of Anatomy and Physiology*, 1871–2, p. 218.

Dr. Schüller (Berlin) performed experiments on rabbits by removing with a trephine a portion of the upper part of the parietal bone without injuring the dura mater, and generally at the same time taking away the cervical sympathetic with the superior cervical ganglion of the same side. He was thus able to observe the vessels of the pia mater, and to notice any changes in their filling. The substances with which he experimented were mustard, nitrite of amyl, ergotin, opium, and chloroform. Small sinapisms produced scarcely any effect on the vessels, the application of large ones, on the one hand, was first regularly followed by dilatation, which was followed by more or less rapidly alternating changes in the calibre of the vessels, and finally by contraction, which often continued an hour and a half after the removal of the sinapism.
—*British Medical Journal*, February 1875, p. 279.

App. IV.

Injuring with a needle a certain spot on the surface of the brain of the rabbit peculiar disturbances occur, above all hæmorrhage in the lungs and in the tissues of the same, often so pronounced that almost the whole lung is traversed by the hæmorrhage.—*Journal of Anatomy and Physiology*, 1873, p. 397.

J. Schrieber has operated on a large number of rabbits with a view to determine the effect of injuries to the brain on the temperature of the body.

The injury was made by means of a lancet-shaped needle introduced through the skull. The temperature was measured in the rectum. From about seventy experiments the author concludes that after injury of the pons in all parts, of [the pedunculi cerebri, of the cerebellum and cerebrum, increase of the body temperature occurred when the animals were protected artificially from losing warmth, that the same results followed unconditionally and constantly on injury to the limit between the medulla and the pons.—*Journal of Anatomy and Physiology*, 1873, p. 398.

1st. Ablation of both spheno palatine ganglia does not affect, in dogs and cats, the sense of taste, in parts supplied by the linguals.

2nd. After section of the chorda tympani, in dogs and cats with cut glosso-pharyngei, the taste was little modified in some cases, notably diminished in others, and completely abolished in one.

. . . .

3rd. . . . After action of the chorda, in cats, dogs, rabbits, and guinea-pigs, degenerated nerve fibres were found in the terminal branches of the lingual as well as in the mucous layer of the tongue and submaxillary gland . . . . .

4th. . . . After section of the chorda in the ear, the central end of this nerve (on the side of its emergence facially) remains healthy.—*Journal of Anatomy and Physiology*, 1873, p. 398.

Curarised dogs in whom artificial respiration was maintained were used for experiment.

After having exposed the glosso-pharyngeal nerve below the base of the cranium, it was tied, and then cut above the ligature, so that its peripheral extremity could be excited by electricity. The effect of the faradisation lasted some time, and could be renewed at pleasure.—*The Doctor*, June 1st, 1875, p. 105.

No. 1. The first pigeon had had the anterior part of both hemispheres removed. The bird was able to fly and walk, and in every respect seemed to have its faculties intact, except that when it tried to peck up food it never succeeded in getting hold of a single particle. That was what he invariably observed when the anterior part of the cerebral lobes had been removed.

No. 2. Showed two pigeons with the posterior part of both hemispheres removed. These were not quite so active as the first bird. He had never seen them attempt to eat at all.

No. 3. There were here two pigeons, in which the right cerebral hemispheres had been removed. One could scarcely be able to detect any difference between them and ordinary pigeons. The removing of one cerebral hemisphere made almost no difference.

No. 4. In those classed No. 4 the left cerebral hemisphere had been removed, and the birds were both quite active. They saw on both sides, and were in the same condition as those in No. 3.

No. 5 was a bird, the right cerebral hemisphere of which he had removed, along with a considerable slice of the upper part of the right corpus striatum. He had shaved off the grey matter that represented the cerebral hemisphere, and had carried the knife deeply through the substance of the brain, so that he was quite sure that he had removed a considerable portion of the right corpus striatum. It would be observed that the bird was blind on the opposite side.

No. 6 showed the left cerebral hemisphere and the left half of the corpus striatum removed. The result was exactly the same (only on the other side) as in the other case. This was a point he was very glad to be able to demonstrate, as he was somewhat doubtful about it for a considerable time. He now knew that if he removed the upper part of the corpus striatum there was loss of vision, in the pigeon at all events, on the opposite side.

No. 7 was a bird from which he had intended to remove the cerebral hemispheres only, but in the operation he unfortunately injured the upper part of the corpus striatum. The forceps with which he removed the skull-cap slipped deeply into the corpus striatum, so that the bird was much more in the condition of pigeons in which the corpus striatum had been injured as well as the cerebral hemispheres. It could fly, it could walk; he did not think it saw or heard, or if it did do so it was only to a small extent. It did not manifest any sign of alarm, and if flung into the air could fly quite well. Birds in that condition very often attempted to take food, but they never pecked up anything, and birds in this condition required constantly to be fed, so that it became a serious matter to keep a number of them.

. . . .

He gave the birds water, but had to introduce the beak; they dipped their heads deeply into the water, and took one drink. Where the hemispheres and corpus striatum had been removed the birds seldom took a second drink.

No. 8. Showed two birds in which the cerebral hemispheres alone had been removed. By these he tried to illustrate that consciousness was apparently not entirely lost; one could still frighten the birds.

No. 9 was a bird exactly in the same condition as the previous two.

No. 10 was a bird on which he had performed the experiment he had described, of injuring the deeper parts of the corpora striata and the cerebral hemispheres by passing a long narrow knife into the side of the head and severing the connection. The corpora striata, though injured, had not been removed. The creature was in a state of deep stupor.

No. 11 was a bird in which both cerebral hemispheres had been injured, but not removed. The bird was still able to fly, but he had observed that the creature had not taken any food since the operation.

. . . .

No. 12. In the cases of No. 12 both birds had a large portion of the cerebellum removed, and he thought it would be found that the faculties of the birds were intact, and that they could fly and walk.

No. 13. Was a bird in great health. On the 5th March he removed from the animal considerably more than half of the cerebellum. At first the bird staggered slightly in its movements, but now it had completely recovered. Within the last six weeks it had been regaining its plumage, and was now as handsome a pigeon as one could see.

Dr. M'Kendrick concluded by stating that if any wished to see him operating, he would have much pleasure in receiving a visit from them at the Laboratory.—*Edinburgh Medical Journal*, 1873, pp. 652–3.

He experimented exclusively on the brain of the rabbit. On puncturing with a fine microscopic needle a spot lying in the interior of the posterior end of the cerebrum the animal sprung from the table and exhibited unusually violent spasmodic movements, which appeared either at the time of puncture or a second or so thereafter (at the latest two minutes), and lasted not longer than three minutes.

. . . .

Many of the animals so injured had meningitis with dippacu, but asph. and death without meningitis was also observed.

. . . .

More than 40 experiments in different ways and different directions were made in the thalamus opticus. Slight disturbance of the superficial layers were without effect. In a few cases the paralysis of the extensors of the finger observed by Schiff occurred. If punctured more deeply and towards the middle line, the limbs of the opposite side were directed towards the middle line. This was specially and almost exclusively observed of the fore limbs. The deviation was the most pronounced the more basal the direction of the puncture. The deviation in all cases was only temporary, disappearing sometimes after a few hours, in most cases after 24 hours. In other cases, immediately after puncture the head was turned to the opposite side, the fore limbs strongly divergent, the one directed outwards, the other (opposite side from injury) towards the middle line. No disturbance of sensibility. [The Editor states that these results are at variance with those alleged to be found by Fournier].—*Journal of Anatomy and Physiology*, 1873, p. 395.

Leyden has made a series of observations upon the movements of the brain, and the blood pressure within the cranium, by means of a manometer screwed into an artificial opening made in the skulls of dogs.—*Dr. Rutherford, Journal of Anatomy and Physiology*, 1867, pp. 358–9.

He gives the results of a number of experiments upon the crura cerebelli of rabbits. The author, working under the direction of Professor Eckhard, has taken great care to ascertain the exact position and extent of the lesion which he inflicted.

. . . .

He gives an exact description of his mode of operating, which will prove of not a little service to those who may wish to perform experiments, whether for the purpose of research or demonstration.

In his experiments on the "tract of the crus cerebelli, formed by the anterior and posterior crus," he found that very much the same effects followed a variety of injuries to the tract comprehending punctures to the depth of one, usually two, millimetres, some in its middle, some on its outer, others on its inner side. Irregular but not violent contractions followed these injuries. Voluntary movement was slightly disturbed. Some animals showed a tendency to lie upon the injured side.

. . . .

In a second series of researches he studied the effect of complete division of this tract. The section was followed by irregular convulsive contractions of varying intensity, extending throughout the entire body.

. . . .

Voluntary movement seemed to be entirely abolished. The animal lay upon the injured side and fell always into this position when it was placed in any other. Some animals were observed in this state for three or four hours, others died from the hæmorrhage, which the operation for exposure of the brain had occasioned.—*Journal of Anatomy and Physiology*, 1869, p. 208.

At the recent meeting of the British Medical Association Dr. Brunton read a paper, communicated by Dr. Ferrier, containing an "Abstract of Experiments on the Brains of "Monkeys, with special reference to the Localisation of "Sensory Centres in the Convolutions." The experiments, which were conducted by trephining and the destruction of the sensory centres by means of a red hot wire, led to the following results: These centres are bilateral, so that when one of the centres of touch was destroyed there was loss of tactile sensibility in the corresponding half of the body. Stimulation of the centre of hearing caused the animal to prick up its ears, as if it heard something, while destruction of the whole of this centre rendered the creature totally deaf. Destruction of the centre of vision corresponding to one eye (*e.g.*, the right) only rendered the animal temporarily blind in that eye, the function, after 24 hours, being carried on by the opposite centre. In the discussion that followed Dr. Nairne pointed out that other observers had arrived at conclusions different from those of Dr. Ferrier, and that the brain of a monkey could not be taken as exactly similar to that of a man; but Dr. Brunton thought the mistake made by German and other investigators who differed from Dr. Ferrier was, that they took the brains of animals lower even than the monkey to correspond with that of man. M. Dupuy had arrived at different results. He said that he had found that when the centres of motion on one side of the brain were removed paralysis followed for a short time throughout the corresponding part of the body, but that when the centres were removed from both sides of the brain there was no paralysis at all.—*Lancet*, No. 2,712, p. 289.

Dr. Brown Séquard, in a lecture before the Boston Society of Natural History, published in the Boston Medical and Surgical Journal, dissents altogether from the conclusions that have been drawn on this subject, and which have lately occupied so much attention.

Our readers will remember that Fritsch and Hitzig, followed by Charcot, Ferrier, and others, concluded that the fronto-parietal convolutions of the brain are the centres for the voluntary movements of definite groups of muscles; but Brown Séquard explains the facts in quite another way.—*The Doctor*, October 1st, 1875, p. 181.

Prof. Hitzig refers to Burdon Sanderson's experiments, and remarks "that the localised points on the surface of "the brain given by B. Sanderson do not correspond with "those described by himself."—*Journal of Anatomy and Physiology*, November 1874, p. 210. [*See also* p. 39.]

On the Suffocation of Animals.

About the year 1860 the Royal Humane Society received several suggestions from Dr. Silvester for restoring suspended animation in persons apparently drowned. Other methods were shortly afterwards placed before the society, on the merits of which that body felt itself unable to decide, and consequently its committee desired the Royal Medical and Chirurgical Society to investigate the several proposals, without indicating the tests which that learned body should apply, or the means they should adopt. It is important to bear in mind that the Royal Humane Society is in no way answerable for the course taken by the Royal Medical and Chirurgical Society, and that they were not even aware, until the delivery of the report from which the following extracts are made, that experiments on animals had been performed by the Committee of Investigation.

Seventy-six experiments were made on animals, in only a few of which anæsthesia was present; and after the terrible sufferings caused by plugging their windpipes to suffocate them, holding them under water, and in some cases restoring them to life for further experimentation, burying their heads in liquid plaster of Paris or mercury, cauterizing their bodies with an iron heated to a white heat, &c. &c., the committee, it will be seen, report that they were unable to recommend any material improvement in the plan adopted by the society.

Report of the Committee appointed by the Royal Medical and Chirurgical Society to investigate the subject of Suspended Animation.

Members of the committee.—C. J. B. Williams, M.D., F.R.S.; C. E. Brown-Séquard, M.D., F.R.S.; George Harley, M.D.; W. S. Kirkes, M.D.; H. Hyde Salter, M.D., F.R.S.; J. B. Sanderson, M.D.; W. S. Savory, F.R.S.; E. H. Sieveking, M.D. (ex officio).

At the first meeting of the committee it was resolved to pursue the inquiry—

By means of experiments upon living animals.

By means of experiments upon the human body.

Two sub-committees were forthwith appointed for these purposes.

. . . .

Report of the Sub-Committee appointed to investigate the subject of Suspended Animation by means of Experiments upon living Animals.

In investigating anew the subject of apnœa by means of experiments on the lower animals, it seemed expedient to observe, in the first place, the principal phenomena of apnœa in its least complicated form, viz., when produced by simply depriving the animal of air.

The following plan of effecting this was adopted:—The animal was secured on its back, and the trachea was exposed by a single incision in the mesial line of the neck. A ligature having been passed round it, it was opened by a vertical cut, and a glass tube, as large as could be conveniently inserted, was passed into it for a short distance downwards, and firmly secured by the ligature. Through this tube, while patent, the animal breathed freely, but the supply of air could be at once completely cut off by inserting a tightly fitting cork into the upper end of the tube. It was ascertained by separate experiments that the tube thus plugged with the cork was perfectly air-tight. . . . . . .

The duration of the heart's action was conveniently ascertained by means of a long pin inserted through the thoracic walls into some part of the ventricles. So long as the heart continued to beat the pin moved, and its motions were thus recorded for some time after the cardiac sounds had ceased to be audible:—

Experiment 1.—A full-grown healthy dog was suddenly deprived of air by plugging the tube placed in the trachea in the manner already described. Its first struggle occurred in 25 seconds; its first respiratory effort was not recorded, its last took place at 4 minutes 40 seconds, and its last heart's beat at 6 minutes 40 seconds, or exactly 2 minutes after the last respiratory effort.

[Eight similar experiments were performed on dogs, rabbits, and one cat. In three of these the plug was withdrawn at about 4½ minutes, but the animals were found to be dead.]

From nine experiments it is seen, that in the dog the average duration of the respiratory movements after the animal had been deprived of air, is 4 minutes 5 seconds, the extremes being 3 minutes 30 seconds and 4 minutes 40 seconds. The average duration of the heart's action on the other hand is 7 minutes 11 seconds, the extremes being 6 minutes 40 seconds and 7 minutes 45 seconds. Lastly, these experiments lead to the belief that on an average the heart's action continues for 3 minutes 15 seconds after the animal has ceased to make respiratory efforts. The extremes being 2 and 4 minutes respectively.

In the case of the three rabbits experimented upon, we find that on an average they ceased to make respiratory efforts in 3 minutes 25 seconds; that their heart's action

App. IV.

stopped in 7 minutes 10 seconds; and, consequently, that the interval between the last respiratory effort and the cessation of the heart's action was 3 minutes 45 seconds.

[Then follows a series of experiments in which the plug was withdrawn at different intervals, and the dogs delivered from the pains of death, and were subsequently operated on again. The committee say :—]

These results lead to the conclusion, 1st, that a dog may be deprived of air during a period of 3 minutes 50 seconds, and afterwards recover without the application of artificial means; and 2ndly, that a dog is not likely to recover if left to itself after having been deprived of air during a period of 4 minutes 10 seconds.

. . . .

For some time after the occlusion of the tube in the trachea the force of the respiratory efforts was so remarkable that it was determined to adopt some means of measuring it. . . . . . . The following were the results :—

Experiment 15.—A medium-sized dog was treated in the above way. The respiratory efforts commenced at 2 minutes 5 seconds. As apnœa advanced they became more powerful, and from 3 minutes 20 seconds and onwards they were very violent till 4 minutes 45 seconds, when they ceased. The needle showed the heart to be moving up to 8 minutes. This dog drew the mercury up the tube, by its violent inspiratory efforts, a height of four inches, and that height was attained in almost the last attempts at respiration, 4 minutes 45 seconds after the establishment of the apnœa. On examination the lungs were found to be congested, but there were no ecchymosed spots or blood in the tubes.

[Then follow similar experiments which produced similar congestion of the lungs.]

. . . .

In the following experiments the great force of the inspiratory efforts was demonstrated in another way.

. . . .

Experiment 18.—A guinea-pig was held so that its nose was immersed in mercury, the animal being upside down, and the nose inserted sufficiently deep in the mercury to prevent the possibility of getting any air. The respiratory efforts commenced at 35 seconds, and ceased at 1 minute 37 seconds. On examining the lungs they were found full of globules of mercury, which had thus been drawn up by this weak animal a distance of an inch or two, and that in spite of gravitation. . . . . . .

Experiment 19.—A terrier was deprived of air by plunging its head into liquid plaster of Paris, the object being, to see, through the whiteness of the plaster, whether any of the fluid obtained access to the lungs. Respiratory efforts commenced at 1 minute 35 seconds, and ceased at 4 minutes, the heart beating till 5 minutes. On examining the lungs the white plaster was found throughout the bronchial tubes.

. . . .

From these preliminary experiments on the effects produced by simply depriving an animal of air, the Committee passed on to the consideration of drowning. The first point to be ascertained was, "for what period can an "animal be submerged and yet recover without the aid "of artificial means?"

Experiment 20.—A medium-sized dog was fastened to a board and submerged in a large bath. It was removed in 4 minutes, but although the heart went on acting for 4½ minutes longer, it neither gasped nor moved.

[Two similar experiments follow.]

. . . .

It having been thus ascertained that 4 minutes drowning kills, it was determined gradually to shorten the time, in order to find out what was the limit of time at which immersion proved fatal.

Experiment 23.—A dog was bound as before to the board and immersed for 3 minutes 15 seconds. On being taken out of the water no respiratory efforts were made; the dog was dead. Bloody froth escaped from its mouth, and its lungs were full of the same material.

Experiment 24.—The same as above, but the dog's head was kept under water 2 minutes only. The dog gasped once or twice, and then died. Lungs full of blood and watery froth."

[Five other dogs were then submerged, and removed at graduated intervals of time.]

. . . .

Having seen that a dog lives after being submerged 1 minute, and dies after being submerged 1 minute 30 seconds, another experiment was performed.

Experiment 30.—A large dog was submerged 1 minute 15 seconds. On being removed, it perfectly and almost immediately recovered.

Thus, then, the remarkable fact appeared that, whereas in simple apnœa recovery may be possible after the deprivation of air for 3 minutes 50 seconds (Experiment 13), and subsequent experiments showed that a dog simply deprived of air almost certainly recovered after 4 minutes, 1½ minutes immersion in water suffices to destroy life.

Now, to what is this striking difference due? With reference to this question the following experiments were performed :—

It was resolved in the first place to eliminate the element of exhaustion produced by struggling; it was thought that possibly the violent struggles of the animal to gain breath when its limbs were confined might exhaust it and hasten the catastrophe.

Experiment 31.—A cat was placed in a cage, and the cage plunged under water. The animal's limbs were at perfect liberty, and there were no violent struggles. After 2 minutes the cage with the cat in it was taken out, and the cat was dead.

Experiment 32.—A dog was treated in the same way, but the cage was kept submerged in the water only 1½ minutes. The dog died. There had been no struggle.

Thus it was seen that struggling had nothing to do with the early fatal result, as it happened equally soon when there were no struggles.

It was next determined to eliminate the element of cold, and for that purpose the following five experiments were performed, in which cold was applied to no part of the surface except the animal's head.

[All the dogs died.]

. . . .

Still further to clear up this question it was determined to place two dogs under precisely similar circumstances, with the single exception that in the one case the free access of water to the lungs should be permitted, and in the other case prevented. The following were the experiments :—

Experiment 38.—Two dogs of the same size were fastened to the same plank and submerged at the same moment, but one of them had previously had its windpipe plugged in the usual way and the other had not. At 2 minutes they were taken out together; the one that had been plugged at once recovered, the other died."

[This was repeated, and the Committee add]—

These experiments satisfactorily show that the difference between apnœa produced by plugging and that by drowning is not due to submersion, to depression of temperature, or to struggles. . . . . . .

. . . .

The fact that animals do not recover after so short a period of immersion is mainly due to the entrance of water.

[Three other experiments were tried with windpipes plugged, after which chloroform was used.]

Experiment 43.—A medium sized dog was rendered insensible by chloroform and drowned. It was kept in in the water for 2½ minutes. Its respiratory efforts were by no means violent, and were in this respect in strong contrast with those of the unchloroformed dogs.

[Two other experiments of a similar kind followed, which proved]—

That by simply depriving the animal of the power of making violent respiratory efforts the period during which submersion may be continued, and yet recovery follow, is at once prolonged. The value and conclusiveness of these chloroform experiments, as showing the essential connexion between the early fatal result in drowned animals and the violent inspiratory efforts that fill the lungs with water, need not be pointed out. . . . . .

Various means of resuscitation were employed in many of the experiments performed by the Committee, and with variable results.

[Then follow seven experiments, in all of which, save one, the animals died.]

Experiment 51.—The same dog as had been previously used in Experiment 13 was again deprived of air, as before, and on the use of Dr. Marcet's instrument 1 minute after respiration had ceased it again recovered.

[This poor dog, therefore, recovered from death twice. The Committee then say]—

No definite conclusion concerning the relative value of the various methods of artificial respiration can be drawn from these experiments.

For this subject the Committee would refer to the "Report of the Experiments upon the Dead Human Body." . . . . . .

. . . .

Many other methods of resuscitation which have been recommended were practised, including actual cautery, venesection, cold splash, alternate application of hot and cold water, galvanism, puncture of the diaphragm.

[Twenty-six experiments under this head were tried, in which the animals were "suffocated in the usual way by plugging their windpipes," and the Committee add]—

Although some of the above means were occasionally of manifest advantage, no one was of such unequivocal efficacy as to warrant the Committee in specially recommending its adoption.—*Report of the Royal Humane Society*, 1865, pp. 31–66.

[Numerous experiments were also made on the bodies of deceased human beings which appear to have yielded excellent results.

Reference to the Reports of the Royal Humane Society will show that with immaterial modifications the method originally introduced to the Society by Dr. Silvester is still in use; such modifications having arisen out of experiments on dead human bodies alluded to, and were not derived from the foregoing painful experiments on animals.]

On the occasion of presenting the above Report to the Royal Medical and Chirurgical Society, the chairman of the investigating committee, Dr. Williams, closed his own summary of proceedings by saying :—" So far then as these " experiments go, they show a great superiority of Dr. Sil- " vester's over Dr. Marshall Hall's ' ready method.' "

Dr. Edward Smith remarked upon the great importance of the present discussion from the interest of the subject, and the fact this being the first occasion on which the society had appointed a committee to make scientific investigation, it might be a precedent for future action. He thought it most desirable that the society should endeavour to accurately estimate the true value of the results which such committees could produce. On the present occasion they had a committee amongst whom were men of world-wide reputation, and a subject of inquiry of the highest interest, and not of greater complexity than would be found in all practical questions in medicine. The Report must be regarded in two aspects : one that of the scientific facts which had been elicited ; the other in their exact application to the purposes for which the committee was appointed—to determine the best methods of restoring the drowned. As to the facts, no one could doubt their extent and interest, the care with which they had been ascertained, and the pains taken to estimate the influence of disturbing causes . . . . . .

It was in reference to the practical object in the appointment of the committee that the Report failed. The committee had not proved that any one of their inquiries was applicable to the drowned human subject. The time during which a man could be immersed in water and recover could not be proved by experiments on dogs, and the committee themselves had shown that all their plans for the restoration of drowned dogs had failed. The committee had in one part of the Report disclaimed any intention to say how far the Silvester method was fitted for the restoration of the drowned ; and yet in their recommendations they advise the use of this method almost exclusively, without having in any experiment tried it, under these conditions. The recommendation to place the body prone and allow fluid to run out of the mouth, was an old recommendation ; but they had inferred and not proved its value, and that only from experiments on drowned dogs which they could not resuscitate. The experiments on dogs had shown that neither hot nor cold water alone had any value as restorative agents, but that the alternative of the two was somewhat useful ; but this alternative had not been recommended for man .

. . . .

Dr. Webster said that he thought the Silvester method was the best, and that the recommendation was very important. He was sorry to hear that the lives of so many dogs had been sacrificed in the experiments. He hoped that in future, if possible, experiments on living animals would be avoided . . . . .

Mr. Charles Hunter said that as he was one of those gentlemen who six years ago conducted the experiments upon the dead body for Dr. Marshall Hall, and upon those experiments the "ready method" was established, he felt called upon for a few words in its defence. He regretted that the committee thought fit to condemn it, and observed that if the Marshall Hall method after all was a failure, the long series of experiments carefully made by him (Mr. Hunter) with others must go for nothing ; and yet the original experiments were much more numerous than those made by this committee, and perfectly conclusive in their general results to those who made and saw them.

. . . .

Dr. Williams would remark in reply to some objections made by Dr. Webster as to the destruction of animal life involved in these experiments that no one experiment had been undertaken without a definite and useful object ; that animal suffering and life had been spared as much as was possible in pursuing the inquiry ; and he did not think that, when it was considered how animal life was hourly and unsparingly sacrificed for the gratification of appetite, there could be any objection to the dedication of a few lives to the elucidation of a subject of real importance to the interests of humanity.—*Lancet*, 2,028, p. 39–40.

[Other similar experiments were made by Dr. Waters, and the results communicated by Dr. Sharpey to the Royal Medical and Chirurgical Society, May 14th, 1861.]

The subjects of experiments were dogs, cats, and rabbits. They were drowned in water varying in temperature from 40° to 50° Fahrenheit, and in one instance 56°. On being removed from the water after every external symptom of life had disappeared, they were opened by the removal of the anterior part of the chest, so that the movement of the heart could be observed . . . .
Thirteen experiments were performed, twelve on rabbits, one on a cat. Of the thirteen, seven were put into the hot bath ; of these six died at periods varying from two to twenty hours after submersion. Six animals were left to themselves ; of these four recovered and two died, both between the eighth and twentieth hour after submersion.

The author believes that the best method of performing artificial respiration we are acquainted with is that recommended by Dr. Marshall Hall.

Dr. Babington was not sure whether experiments upon dogs respecting warm baths were applicable to human beings. The warm bath would probably be more injurious to asphyxiated dogs from the fact that the skin of the dog was remarkably thick, and it was known that he did not perspire. He (Dr. Babington) did not know whether cats were subject to perspiration.

Dr. Waters in reply said that of the experiments he had detailed some were performed about four years ago. The attention of the profession was at that period directed to the subject by the late Dr. Marshall Hall. He (the author) at that time brought the results of his experiments in reference to the hot bath before the committee of the Liverpool Royal Humane Society. This society had previously adopted the rules of the Royal Humane Society of London. The committee of the Liverpool Royal Humane Society referred his plan to the Liverpool Medical Society for their opinion. The result was that the plan was recommended, and it was therefore adopted. Unfortunately no record whatever had been kept of the cases thus treated, so that no practical test of the working of the method was attainable. . . . . The experiments of Mr. Erichsen and those performed by himself tended to prove that the heart contracted for some time after complete asphyxia.—*Dr. Waters, Lancet*, No. 1,969, p. 513 and 514.

[After all these valuable experiments the learned Doctor comes to the following honest, sensible, conclusion.] .

. . . .

In considering the question of the deviation of the heart's beat in asphyxia, and the possibility of restoring animation in the affection, it is very desirable that if we err we should err on the right side. It is better that we should make fifty ineffectual attempts to save life, acting on the supposition of the prolonged duration of the heart's beat, than that we should suffer one life to be lost by allowing the opposite assumption to paralyse our efforts.—*Dr. Waters, Lancet*, No. 1,977, p. 60.

App. IV.

B.

EVIDENCE OF PROLONGED PAIN.

[Some of the following show pain only for a short time, but they could not well be eliminated from the series in which they appear.]

This pamphlet contains the results obtained by burning and scalding about thirty dogs, in regard to, 1st, the local temperature produced by burning certain substances upon the surface of the body; 2nd, the manner in which this local increase of temperature extends over neighbouring parts, and the mode in which this increased temperature dies off; 3rd, the histological alterations produced locally and generally by burns and scalds. Medium sized dogs alone were made use of. Some of these were narcotised by the injection of half a drachm of tincture of opium into the crural vein, and others by chloroform inhalations. The latter method was employed when the blood was to be examined, the former in other cases. The burns were produced by sponging the chest and bellies of the dogs with oil of turpentine five or ten times in quick succession, setting fire to it each time, the scalds by pouring over similar parts eight ounces of boiling water nine times in quick succession.

The results obtained were:—1st, all the dogs died either in a few hours or at the latest after five days.

2nd. Excision of a portion of skin corresponding in position and extent to that burned, had no injurious effect on three dogs on which it was performed. For the first few days the wound was covered with sponge, no attention was subsequently paid them, and the wounds healed most kindly.

3rd. In three cases the burned portion of skin was *excised* two, five, and fourteen hours after the burning. All the three dogs died 24 hours after the burning.—*Edinburgh Medical Journal,* 1868–9, p. 1026.

To a third I gave 193 drops of spirits of wine within the hour, but warded off immediate death by means of strychnine. The animal died in six weeks. On making the post-mortem examination, I found slight congestion of the dura mater, but severe congestion of the liver, which was black, and literally rotten. The intestine was also severely congested, doubtless in a great measure from the action of the strychnine. In this case a large amount of alcohol was kept in the blood of the rabbit by artificial means (equal to seven to eight pints in an ordinary sized man). The result was, that there was not oxygen available to the extent required for its rapid combustion and elimination; hence the severe mischief set up by its presence.—*Mr. Lucas, British Medical Journal,* No. 724, p. 612.

Good results are yielded more easily by a feverish than by a healthy animal. For these experiments strong guinea-pigs, rabbits, or dogs of the same origin and of the same quality have been used. Under their skin some cubic centimeter of ichor or putrifying blood was injected. After thus proceeding, the temperature of the animal rises several degrees, and all the symptoms appear which are to be observed in human beings suffering from putrid fever. If the quality of the poisonous substance be right the animal expires in a few days.—*Nature,* 216, p. 132.

The author, Dr. Moritz Roth Greipwold, could not succeed in producing ulcers by tying or occluding vessels, but in a number of rabbits he produced ulcers, closely resembling the ordinary perforating ulcers, by administering a small fragment of lunar caustic, the ulcers were mostly along the lesser curvature and the back wall. When examined within a few days of the administration of the dose the surrounding mucous membrane was found swollen and inflamed.—*Edinburgh Medical Journal,* Vol. 18. p. 951.

Physiologists have been accustomed to examine the action of the heart in cold-blooded animals to determine the laws that regulate its movements. Dr. Hope performed a number of experiments on frogs and on turtles, to perceive the manner in which the auricle and ventricle contract and dilate; and Professor Muller, of Berlin, from the observations he made on the movement of the heart in frogs, states a general law respecting the rhythm of the heart. Oesterreicher placed a body on the heart of a frog heavy enough to press it flat, but sufficiently small to allow the heart to be observed, and it was seen that the body was lifted during the contraction of the heart, but that during its extension it remained flat; . . and Dr. John Reid endorses the opinion as a legitimate deduction applicable to warm-blooded animals, and physiologists still continue to pursue their investigations in the action of the heart in cold-blooded animals. . . .

Page 412. We consider then that we have proceeded on sound physiological principles in the series of experiments that we instituted on the denuded heart of turtles during the highest temperature of the season, to determine the cause of the sounds of the heart; and we are decidedly of opinion that these animals afford a much better field for investigating the action of the heart and arriving at a correct knowledge of the cause of the sounds than is obtained from the denuded heart of warm-blooded animals. In the warm-blooded, as in the dog and ass, the operation of laying open the thorax and denuding the heart produces a great shock on the system, and the fact that you require to maintain artificial respiration to continue your investigations for any length of time, interferes materially with the action of the heart, rendering it weak and irregular, and the sounds indistinctly heard. But in turtles the effect of the operation on the action of the denuded heart appears but slight.

If the temperature of the body be high the heart continues to pulsate with energy and in a normal and regular manner after being exposed, and the *animal* will *survive* for *several days,* affording an ample field to observe true action and investigate the cause of the sounds.—*Dr. Paton, Edinburgh Medical Journal,* 1873–4, pp. 407–12.

Who would have supposed that a rat's tail after removal of the skin might be kept in a glass tube for 62 hours at 15–17° Fahr.; or kept for a still longer period in moist air at 121° Fahr.; or after being subjected to a temperature 31° below the freezing point; or, finally, after being dried in an air-pump over sulphuric acid, and enclosed in a glass tube for three days, then exposed to a temperature of 175° Fahr. in a hot air chamber, and again enclosed in a glass tube for four days,—who would have supposed that the unfortunate tail might be subjected to such a treatment and yet live on its being placed below the skin of the back of a rat. These remarkable facts regarding the vitality of the tissues have been ascertained.

. . . .

I had an opportunity of witnessing the results of two such experiments. [Amputating tails of animals and afterwards engrafting them on other animals.] In one the revived tail had been frozen; in the other it had been kept in moist air for three days at 121° Fahr.; on the animals being injected it was found that there was free vascular communication between the engrafted tail and the surrounding tissues. He moreover finds that the tissues which have been subjected to such modifying influences are liable to fall into certain diseased conditions, the progress of which may be traced by killing the animal at different stages. In the prosecution of this research he is still engaged. He has also succeeded in joining together animals, not only of the same, but of different species, not not only rats to rats, but actually a rat to a cat. He effected this by denuding corresponding parts of their sides, and then uniting by means of sutures the skin of the one animal to that of the other, and tying the two animals together so as to prevent their tearing themselves apart. The practical importance of such researches does not require to be dwelt upon.—*Dr. Rutherford, Journal of Anatomy and Physiology,* 1867, p. 163.

His investigations have extended over many years; and he has experimented upon cats, rabbits, crows, fowls, pigeons, and various small birds. Of all these he finds young cats the best adapted for research, as the nerve trunks in those animals contain very little connective tissue in their interior. The mode of operating consisted either in dividing the nerve with the knife, or in applying a fine silk ligature for a few moments, which is almost equally efficacious in cutting through the axis cylinders. The changes induced were examined at various intervals of time ranging from two hours to six months, and both in the fresh state and after maceration in different preserving fluids.—*Lancet*, No. 2,560, p. 421.

Vulpian removed completely this ganglion in dogs, on the left side. At the end of from ten to fifteen days the animals were curarised and artificial respiration kept up. The skin and subjacent tissues of different parts of the body were stimulated by strong induced currents. Each time the pupil on the left side dilated a little from the quarter to a third of its radius.—*Journal of Anatomy and Physiology*, 1873, p. 398.

After extirpating the superior cervical ganglion in a dog, it was curarised after the lapse of from 10 to 15 days. Artificial respiration was kept up, and the skin of the abdomen and hinder extremities were stimulated with strong induced currents, each time both the pupils became dilated, even that corresponding to the side operated on, and which is inervated from the upper cervical ganglion (a part of the sympathetic was destroyed at the time of extirpation).—*Journal of Anatomy and Physiology*, November 1874, p. 214.

A. Billder excised a piece (1·5 c. m. in length) of the left cervical sympathetic from a half-grown rabbit.

. . . .

In about a month the rabbit had grown just as the other rabbits, and appeared quite sound. The left pupil was only half as large as the right, and the left eyeball projected much less from the orbital cavity than the right. The left ear was distinctly broader and larger than the right, and was more hyperæmic and warmer.

In a fortnight later the difference in size was more striking.—*Journal of Anatomy and Physiology*, November 1874, p. 214.

Dr. Hjalmar Heiberg's (of Christiania) paper on the regeneration of the corneal epithelium, which leads off the serial, contains several points. . . . .

His mode of procedure was to scratch the surface of the cornea with a cataract needle in animals (frogs, birds, rats,) and after the lapse of from 18 to 40 hours to remove the eye.—*Lancet*, No. 2,501, p. 197.

If one continues to administer a daily dose of alcohol sufficient to bring on intoxication, one remarks in the dog from about the fifteenth day a nervous excitability of quite peculiar character. The animal is melancholy and uneasy; he listens, the least noise makes him start; when the door is opened, seized with fright he runs and crouches in the darkest corner of the room; he no longer responds when patted, he runs away and tries to bite when one attempts to take hold of him, and utters sharp cries at the mere threat of blows. This irritable and timid condition increases each day, and from the end of the first month, illusions and hallucinations becoming added to it, it is transformed into a veritable delirium. In the middle of the night he utters plaintive moans, or even whilst all is quiet he begins to bark, the cries becoming louder and more frequent as if an enemy were approaching; speaking or calling does not reassure him, one must interfere with a light. At last, during the day he growls without cause; then, thinking that he is pursued, he cries out, runs scared hither and thither, with his head turned back and snapping in the air.—*Dr. Magnan, The Lancet*, No. 2,664, p. 411.

What we see in the dog, in some cases, after intravenous, subcutaneous, or stomachal injections of essence of absinthe is as follows:—In the interval between two epileptic attacks, and sometimes before the convulsive symptoms, or even without convulsions, the animal is seized with an attack of delirium. All of a sudden he erects himself on his paws, the hair bristles, the look becomes wild, the eyes injected and brilliant, staring at some particular spot where there is nothing apparent to draw his attention; he barks furiously, advances and retires as before an enemy, with open mouth he throws his head suddenly forwards, and immediately shuts his jaws and shakes them from side to side, as if he wished to tear his prey in pieces. This attack of delirium may recur several times; then the effects pass off, and the animal becomes quite calm.—*Dr. Magnan, Lancet*, No. 2,664, p. 411.

At a recent séance of the Académie des Sciences, however, Mr. Ranvier adduced certain experiments, which, if they do not absolutely disprove the ordinarily received views, at least are strongly suggestive of the suspicion with which we should regard all traditional dogmas, however high the authority by which they are supported.

The views above mentioned seem to date from the experiments made by our countryman Richard Lower, who, in his "Essay on the Heart and on the Colour and Movement of the Blood," first showed that tying the vena cava was followed by ascites, and ligature of the jugular veins by œdema of the head, with copious flow of saliva and tears, resembling, as he says, the salivation produced by mercury, terminating in two days in suffocation. . . .

Mr. Ranvier, however, appears to have been dissatisfied with the accepted views on the subject, and proceeded to repeat the second experiment of Lower. He tied the two jugular veins at the inferior part of the neck in a dog and in a rabbit. To his surprise, however, these animals presented no discharge of tears, no salivation, nor any œdema of the head. In other experiments he ligatured the femoral vein immediately below the crural ring in the dog; but here again no œdema occurred either on the day of operation or at any subsequent period. These results consequently were in accordance with those observed by Hodgson in man. Lastly, he applied the ligature to the inferior vena cava, but still no œdema occurred. He then conceived the idea of favouring the production of dropsy by paralysing the vaso-motor nerves, and recalling the experiments and observations of M. Claude Bernard he divided the sciatic nerve on one side in a dog whose vena cava inferior had previously been tied. On this side a considerable degree of œdema immediately supervened, whilst the opposite hind limb remained in its ordinary condition.

This remarkable experiment was performed three times, and on each occasion with the same results. From these experiments M. Ranvier believes that he is justified in concluding that mere ligature of the veins does not in the dog at least produce œdema, but that after obliteration of the veins, dropsy may be caused by section of the vaso-motor nerves.—*Lancet*, No. 2,428, page 383.

Dr. Tschaussow has lately made some observations of interest on the inflammatory process as observed after ligature of the artery supplying the inflamed part, and his results are recorded in a recent number of the Centralblatt. He remarks that, under ordinary circumstances, the several stages of an acute inflammation proceed with such rapidity that it is difficult, if not impossible, to define their limits. It was therefore suggested by Dr. Samuel that means should be adopted by which the progress of the inflammation might be retarded, and to this end it was practicable either to apply cold or to ligature the artery supplying the part with blood. These suggestions were carried out by Dr. Samuel himself to a certain extent. The part investigated was, for the sake of convenience, the ear of the rabbit, and in this inflammation was established, after ligature of the common carotid or auricular arteries, by the rubbing in of croton oil. Dr. Samuel found that in the first stage (within twenty-four hours) of acute inflammation there first occurred retardation, and subsequently arrest, of the venous circulation; white "vesicle" appeared in the veins. Then followed a second stage, characterised by congestion of the arteries, which previously presented no visible change whatever. This was followed by intense arterial congestion with exudation, cloudiness, and swelling of the tissue. By means of this secondary congestion the arrest of the circulation was overcome, or, if not overcome, the death of the part was the result.—*Lancet*, 1869 No. 2,416, p. 849.

Ablation of the cerebellum is therefore equivalent, for a time, to extensive irritation of the organ, but this gradually subsides, and in those that long survive the effects of the operation may wholly disappear. The only permanent change Mr. Mitchell thinks he has seen is, that in all the birds there is an incapability of prolonged exertion, the animals tiring much sooner than their uninjured fellows, but beyond this, no locomotor defect, no alteration either in sensibility or in the sphere of emotional activities is perceptible. Vomiting is an occasional but transitory symptom. Diarrhœa commonly follows ablation, and persists for a week or more.

After having concluded these investigations, Dr. Mitchell examined the effects of freezing the various parts of the nervous system, and found that complete refrigeration of the cervical region of birds induced asphyxia by paralysis of the respiratory nerves, but mere chilling produced gasping respiration, convulsions, backward movements, and other symptoms which strongly reminded him of the effects of cerebellar lesions. Freezing the cerebellum induced precisely similar symptoms, and this he attributes to the congestion which cold secondarily occasions acting as an irritant along the plane of junction of the frozen with the unaffected parts, and this view is supported by the fact that direct irritation of the cervical spinal cord with capsicum occasions the backward movements after some hours, the effect being also rather persistent. Dr. Mitchell made the remarkable discovery, that cold applied suddenly to definite tracts of skins in pigeons gives rise to exactly the same retrogressive movements as when the correspondent spinal regions are frozen, and when the right or left side of the crop was frozen, the pigeon walked to the side opposite to that frozen. But a still more curious point remains to be noticed, namely, that in animals from whom the cerebellum had been removed the effects of congelation and of irritants were still the same, the birds being yet capable of exhibiting in perfection the retrogressive acts, convulsions, and lateral walking.—*Lancet*, 1869, No. 2,393, p. 57.

In a memoir recently published by Herr Dr. Zalesky, this physiologist records some experiments which seem to prove that urea is found in the kidneys, and not in the blood. He removed the kidneys from various animals, and examined the blood subsequently for urea, but without finding larger traces than usual. In animals, however, in which (without removing the kidneys) he placed a ligature upon the ureters, he found the proportion of urea in the blood largely increased, as the consequence of several experiments upon birds, reptiles, and mammals.—*Lancet*, No. 2,218, p. 239.

Experiment 6.—A very large and powerful dog, in admirable condition, was subject to a rigid fast for seventy-two hours, three full days.—*Dr. Harley, Lancet, No.* 1,938, p. 388.

Dr. Harley briefly related several of the experiments he had performed, some of which lasted but twenty-five minutes, while others had extended over a period of eighty days. In the first case, one grain of common arsenic was injected into the jugular vein of a cat; in three minutes convulsions commenced, and in the short space of twenty-five minutes the animal was dead. In the case referred to where the animal lived eighty days, the dose was gradually increased from a quarter of a grain to one grain; in all forty-nine grains of the poison were taken, and at death the animal presented in a marked degree the effects of chronic poisoning.

In reference to experiments on animals the author said that he did not pretend that poison could produce exactly the same effect as in man. There was, however, probably greater similarity than was generally supposed. He thought that as a rule the mineral poisons acted on animals in the same way as on man.—*Dr. Harley, Lancet*, No. 1,995, p. 499. [*See* Langley, p., 7, Marcet, Thorowgood, and Lancet, p. 25, Yeo, p. 38, and Moore and Reynolds, p. 39.]

I have also ascertained that in frogs rendered blind these experiments give the same results.—*Dr. Brown Séquard, Lancet*, No. 1,818, p. 4.

Dr. Soutougnine (physician to the Cesarewitch) also injected the blood of a rabbit into the veins of a dog with the effect of causing bloody urine, wasting and death.—*Dr. Madge, British Medical Journal*, No. 680, p. 42.

In the first eleven cases blood of various kinds of animals was transfused, in all cases defibrinated. The blood of dogs was transfused in two cats, and in seven dogs the blood of calves was transfused, cat's blood was thrown into one dog, and dog's blood into a sheep. In two cases in dogs, death took place from twenty to twenty-two hours after transfusion of calf's blood; and the author in one case attributed the death to paralysis of the heart, whilst in the second there was œdema of the brain and lungs. In all the rest of the cases the transfusion of defibrinated blood by different species of animals was not only well borne, but it gave the animals strength, like the blood of their own species. The author found the foreign blood to be assimilated in from twenty-four to sixty hours.

In eight cases, again, the leg of a dog was amputated and great anæmia was caused. In the space of from ten to thirty minutes after the amputation defibrinised blood from calves or sheep was injected. In all cases death was the result from hæmorrhage from the stump. Of two dogs which had blood transfused into them twenty-four hours after amputation, the first outlived the operation, whilst the second died on the eleventh day of acute purulent œdema and of septicæmia. In one case transfusion of defibrinated calf's blood was made two and a half days before the operation, and it got well in twelve days.—*The Doctor*, May 1st 1874, p. 81.

From his paper we learn that Dr. G. R. Cutter has informed him of some experiments made in Arnold's laboratory, Heidelberg, on dogs, rabbits, and frogs, the retinal vessels being measured before, during, and after the administration of quinine. A gradual but marked diminution of the arteries took place. Before death they became mere threads; the veins were also diminished in diameter; the animals often became blind; and the retina was anæmic in the highest degree. Inflammatory dilatation was lessened, and the wandering of the corpuscles retarded.

. . . .

Chirone's experiments further show that quinine exercises a powerful influence over the heart. A frog poisoned with the drug is able to leap or jump a considerable time after the heart has been arrested in full diastole.—*The Doctor*, October 1st 1875, pp. 189–90.

In order to test the statement of Reitz and Oertel that true croupous inflammation can be excited by dropping ammonia into the air passages of animals, H. Meyer introduced into the air tubes of dogs and rabbits a solution containing in each 100 cubic centimetres 8·96 grammes of ammonia, eight to ten drops being used for dogs, and from three to six for rabbits. He then investigated the changes found either on killing the animals, or on their spontaneous death, which took place generally within a period varying from forty-eight to seventy-two hours. From two to five hours after the injection, the mucous membrane became swollen and red, and studded with numerous ecchymoses; colourless blood corpuscles lay around the vessels. From the surface, a fine membrane could be raised, consisting essentially of epithelial cells; under it, the basement membrane lay exposed. The epithelial cells had undergone very various changes of form, being partly cup-shaped, with an opaque granular protoplasm, without cilia; most of them, however, were reduced to fragments. Along with them were a few pus corpuscles and a few fungous growths of the most various forms. The whole was imbedded in a mass of mucus which, under the action of alcohol, formed a fine network or ran into nuclei. The trachea was filled with bloody mucus as far as the larger bronchial tubes; the mucous membrane of the larynx was pale and œdematous. After ten hours the frothy secretion was replaced by a muco-purulent one, becoming purely purulent in the deeper part; the false membrane was yellower, and consisted almost exclusively of round cells, nucleated adipose cells, free nuclei, fat nuclei, cryptogamic growths, and mucus. Under the action of hardening materials, the latter formed a delicate trellis-work, which, with its enclosed cells, closely resembled the network present in croup. The mucous membrane was enormously hypertrophied, and presented an increased infiltration of proliferating cells. The mucous membrane of the larynx was pale and remarkably swollen; the epithelium was in part fatty. If the animals died or were killed when the disease was at its highest point, the air tubes were found to be lined with a nearly tubular membrane, from half a centimetre to a millimetre in thickness, extending nearly as far as the bifurcation, and ending here in a dirty yellow puriform mass.—*British Medical Journal*, No. 707, p. 82.

Dr. Chrzonzewski details some experiments in the Wiener Med. Wochenschrift. The anus and urethra being covered up, and in thick-haired animals the skin shaved, in a two per cent. solution of muriate of morphia, the animal died in eighteen to twenty hours; in one per cent. of strychnia, in two and a half to four hours; in one per cent. of nicotine, in one to one and a half hours; in two per cent. of cyanide of potassium at 2° C., in a half to one third of an hour; more quickly at a higher temperature . . . . .

In order to test the method of absorption such experiments as the following were instituted:—Ferro-cyanide of potassium was injected into the vein of a dog, and the animal placed in a bath containing an iron salt, in three to five hours the veins and capillaries of the skin were stained an intense blue, the cellular tissue remaining colourless.—*The Doctor*, April 1st, 1872, p. 70.

The cause of death after the skin of animals has been covered with varnish has been the subject of much discussion. It has been ascribed to asphyxia, reduction of temperature, retention of perspiration, &c. Dr. Feinberg has repeated the experiments, and he considers that the symptoms are due to a general dilatation of the entire vessels of the body.—*The Doctor*, February 1st, 1872, p. 38.

Dr. P[illegible] experimented on rabbits by suppressing the function of the skin by painting them partly over either with oil, gum, varnish, &c., or producing inflammation of the skin by croton oil and turpentine. He experimented on thirteen rabbits. Two of them died after forty hours, four in the first twenty-four hours.—*Mr. Purdon, Doctor*, February 1st, 1872, p. 39.

The Lancet, No. 2,713, contains an article approving experiments made by Dr. Sokoloff on rabbits and dogs by painting their skins, after these had been denuded of hair, with substances to prevent transudation of moisture.

Various varnishes were employed, but it was found that the most satisfactory application was a thick oil. A comparison of a considerable number of experiments showed that the effect on the internal temperature varied according to the area of the skin on which the application was made. If the application was a very partial one, during the first days there was either a slight elevation of temperature (in the dog) or a slight fall (in the rabbit) but the deviation from the normal was never considerable. Subsequently, there was a slight rise, followed by a fall, and simultaneously a series of symptoms indicated the commencement of serious organic mischief, general weakness, loss of appetite, evidence of weakened heart, dyspnæa, &c., and these symptoms continued till death.—*Lancet*, No. 2,713, p. 318.

He has thus removed from rats and dogs, after opening the abdomen, a part of the liver by means of a galvano-caustic knife. By proceeding slowly there was no bleeding, and the animals completely recovered.

The autopsy of these animals was made three weeks after the operation. We found in a rat from which a notable part of the liver had been removed, and which had not presented any symptom of jaundice, the liver quite healthy and in the part cut numerous and strong adhesions to the stomach and a part of the intestines.

. . . .

We also removed a portion of the kidney from two dogs. In one we cut the kidney through almost its entire length, opening up the pelves. It was impossible quite to obliterate these, and as the urine dropped into the peritoneum the animal died in forty-eight hours. In the other dog we made a very deep cut in the cortical part, without opening the pelvis. This dog lived ten days without presenting symptoms of gravity, on the tenth day it fell sick and died rapidly.

. . . .

With other ideas, but always in order to show the innocuity of galvano-cautery, we pierced right through the thorax of a guinea pig with a large needle, and at once cauterised this wound in the lung by means of a platinum thread made red hot by the galvanic current.—*Dr. Onimus' Lectures, The Doctor*, June 1st 1874, p. 104.

When rabbits are starved, glycogen disappears from the liver. In such rabbits puncture of the fourth ventricle does not produce diabetes. After a few injections of cane sugar into the stomach of starved rabbits, glycogen reappears in the liver. Injections of water, albumen, or fat, have not this effect. If the fourth ventricle be punctured before the injection, no glycogen appears in the liver, and no sugar is found in the urine. Poisoning by woorara produces diabetes in starved rabbits, although puncture of the fourth ventricle does not. After poisoning by woorara, injections of sugar into the stomach do not produce glycogen in the liver, but sugar is abundantly found in the urine.—*Dr. T. L. Brunton, British Medical Journal*, No. 686, p. 222.

Dr. Pavy, in his lectures on diabetes, mentioned that, when he divided the superior cervical ganglion of the sympathetic, he could, at will, produce diabetes in the lower animals, but that he found it impossible to keep the subjects of the operation under observation for any length of time, because they all died in a few days with pleurisy and pneumonia. The same lesion which produced the diabetes, caused also the inflammatory affections of the lung.—*Mr. Moon, British Medical Journal*, No. 691, p. 428.

Dr. Hughes Bennett (of Edinburgh) contributed some "New Investigations to determine the amount of the Bile secreted by the Liver, and how far this is influenced by Mecurials." He stated that although much had been written regarding the functions of the liver, and the action of mercurials upon it, very little exact information existed on the subject. Last winter a committee was formed in Edinburgh to re-investigate the amount of bile secreted in health, and after the administration of mercurials. This committee was composed of Professors Christison and Maclagan, Drs. Rogers, Rutherford, Gamgee, Frazer, and Professor Bennett, the chairman and reporter. After studying all that had been previously published by authors, the committee made further experiments on dogs, animals best suited for the purpose. The results of four series of these experiments were given as to the amount of bile secreted, with and without mercury. In each case the weight of the animal was taken, a biliary fistula formed, the amount of food taken and analysed, and the secretion of bile for twenty-four hours measured.—*The Lancet*, No. 2,299, p. 375.

Of these, the mercury report of Dr. Hughes Bennett, which had also been brought forward at Oxford, and was now again submitted to medical criticism, was perhaps the most interesting. . . . .
And we are informed that there was an indisputably superior weight of opinion in favour of the conclusions expressed in the report, namely, that in dogs mercury is entirely incapable of increasing the secretion of bile, and that the analogy is sufficiently good to allow of our concluding the same of its operation in man. Now, in commenting on this conclusion, and the various arguments which have been urged against it at Norwich and elsewhere, we must in the first place express our entire conviction that the experiments themselves were performed with an amount of care and labour which renders them perfectly reliable, and for which Drs. A. Gamgee and Fraser deserve the warm thanks of the profession. It seems to us established beyond a doubt that mercury never increases, and that in large doses it seriously diminishes, the flow of bile in healthy dogs. And in spite of the objections which have been made about the infeasibility of arguments drawn from experiments on dogs (objections which are chiefly put forward by persons who are not familiar with experimentation on animals, as Dr. Gamgee rightly observed), we consider that the inference of a similar ineffectiveness of mercury as a cholagogue to healthy human beings is quite legitimate.—*Lancet*, No. 2,348, p. 285.

Professor Bennett read a "Report on the action of Mercury on the secretion of bile," in which he reiterated the statements made at the meeting of the British Medical Association at Oxford, viz., that in whatever doses mercury may be administered it fails to influence the secretion of the bile; in fact it diminishes it. An animated discussion followed, in which Dr. Crisp called in question the accuracy of the Committee's facts, because the dog was not at all like man in the general formation of his alimentary canal. In their wild state dogs are carnivorous, in domestication they become omnivorous. He agreed with Mr. Flower that the pig would be a better animal for experiment than the dog. He thought we were bound to analyse with great care the nature of these experiments, and should not hurriedly abandon our long entertained views regarding mercury.—*Lancet*, No. 2,348, p. 292.

Professor Gross, of Philadelphia, said that whilst acknowledging the accuracy of the facts, he was yet not disposed to ignore the action of mercury. An experiment on a dog was one thing, but a careful observation on the human frame performed at the bedside was another and wholly different one.—*Lancet*, No. 2,348 p. 292. [*See also* p. 38.]

I have found that, in cats, the glycogen disappears from the liver within a few days after the bile-ducts have been tied; and also that, on the fifth or sixth day after ligature of these ducts, irritation of the fourth ventricle is not followed by the appearance of sugar in the urine. It would appear, therefore, that within a few days after complete obstruction to the gall-ducts, the liver ceases to secrete glycogen.—*Dr. Wickham Legg, British Medical Journal*, No. 698, p. 646.

App. IV.

Schiff found that diabetes could be produced by division of the anterior columns of the spinal cord between the medulla and the fourth cervical vertebra. This lasted for days or weeks, in fact till the animal died.—*Dr. Brunton, British Medical Journal*, No. 680, p. 40.

During the past winter I have made several observations upon the changes which follow ligature of the bile ducts in animals. The animals used were cats; these seem to survive the operation better than dogs. Most observers find that dogs live only five to ten days after. The way in which the ligature was applied was as follows:—The animal was first secured in a Czermak's holder, and chloroform given largely so as to secure a deep narcosis. This latter point is worthy of attention, for, unless the animal be completely under the influence of chloroform, the bowels are apt to prolapse, and interfere with the success of the operation. Cats, it is well known, require a large amount of chloroform. A cut is then made through the linea alba, from the xiphoid cartilage downwards, for about two inches. Unless the animal be very large and fat a longer cut is unnecessary. I have never made any longer than two and a half inches. Pushing aside to the left the stomach and duodenum, and raising the free edge of the liver, the bile ducts are seen coming from the liver and gall bladder. They much resemble a vein in appearance, but they will be known by their insertion into the duodenum, bifurcation, and connexion with the gall bladder. A ligature is then put around the common duct and tied close to the duodenum; another is tied tightly on the duct, about half an inch nearer the liver, and the duct between the two ligatures divided by a pair of scissors, the vessel being held out from the portal vein for that purpose. In two of the cats the bile found its way again into the intestines; in the latter operations, therefore, I removed altogether about half an inch of the common duct, as is done in making biliary fistulæ. The belly walls were then brought together with ordinary sutures. It is well to place these close together, as I lost three of the cats from the giving way of the sutures and consequent prolapse of the bowels.

. . . .

Had I to repeat these experiments I should choose only young, not fully grown, animals, and a warm time of year. Though the cats were kept in a warm place, and the January of this year was mild, yet three of them were found dead one morning after a slight frost in the night.

. . . .

Experiment I., January 24th, 1873.—Large tabby cat weighing $8\frac{1}{2}$ lbs. (3,855 grm.), very fat; bile ducts tied double and cut. The cat died probably on January 26th.

. . . .

Experiment II., January 24th, 1873.—Black she cat weighing 6 lbs. $6\frac{3}{4}$ ozs. (2,757 grm.) Bile duct tied double, but not cut. Animal pregnant. The cat died on January 26th, examined January 28th.

. . . .

Experiment III., February 3rd, 1873.—Large tabby cat weighing, immediately after operation, 7 lbs. $3\frac{1}{2}$ oz. (3,265 grm.) Animal very fat; bile duct tied, but not cut. February 6th.—Cat seems to be dying; it is unable to stand, but lies on its side, mewing. February 7th.—Found dead at 11 a.m. in same place where left yesterday.

. . . .

Experiment IV., January 3rd, 1873.—A young cat. The common bile duct tied twice and divided. Cat found dead on morning of 7th. Cause of death prolapse of bowels.

. . . .

Experiment V., January 7th, 1873.—White cat with yellow brown markings, very old, only one canine tooth, weighing $6\frac{1}{4}$ lbs. Bile duct tied double and cut. January 9th, cat very feeble; no suppuration of wound. Cat found dead at 10.30 a.m. on January 11th.

. . . .

Experiment VI., February 3rd.—A cat not fully grown; very wild; scarcely any fat on body; weighing, immediately after the operation, 3 lbs. 5 oz. (1,501 grm.) Bile ducts tied double, but not cut. The animal nearly died under the chloroform, but recovered with artificial respiration. Cat last seen alive on February 7th; no jaundice of conjunctiva. Found dead on morning of February 12th, and already much decomposed. Cause of death, prolapse of bowels.

. . . .

Experiment VII., January 6th.—A whitish cat, with grey spots, weighing $5\frac{3}{4}$ lbs. (2,598 grm.) Bile duct tied double and cut. January 8th.—Cat feeble, belly wound suppurating. January 10th.—Less suppuration; cat livelier. January 13th.—Cat found dead in morning, with bowels prolapsed. Examined immediately; weight $4\frac{1}{4}$ lbs. (1,917 grm.)

. . . .

Experiment VIII., February 12th.—A tabby cat, weighing 6 lbs. $11\frac{1}{2}$ ozs. (3,060 grm.) The bile duct tied close to the duodenum and above, so that about seven or eight millimeters were cut out. The cat was found dying at 10.30 a.m. on February 19th. Examined immediately; weight 5 lbs. $13\frac{1}{2}$ oz. (2,620 grm.)

. . . .

Experiment IX., February 12th.—A very large tabby cat, grey and black, weighing 7 lbs. (3,175 grm.) Very little fat on body. The bile ducts tied double, and about four or five millimeters of the duct between the ligatures cut out. In opening the belly the liver was pricked; there was free bleeding, which presently stopped of itself. The animal is said to have died on February 21st. It was examined on February 22nd, weight 5 lbs. $2\frac{1}{2}$ oz. (2,325 grm.)

. . . .

Experiment X., June 10th.—Black and white cat. Common duct tied double, and about five millimeters of the duct cut away. Cat found dead on morning of June 23rd. No jaundice of lips and mouth.

. . . .

Experiment XI., January 9th.—Black tom cat, weighing 6 lbs. $1\frac{1}{4}$ oz. (2,725 grm.) Bile duct tied double and cut. January 22nd.—The conjunctivæ are now noticed for the first time to be yellow. The cat is growing thinner every day, but has eaten very little since the operation. The wound looks well, and there is no suppuration. January 25th.—This day all the remaining stitches taken out of wound; it is firmly united; weight of cat 3 lbs. $7\frac{1}{2}$ oz. (1,040 grm.) The cat died at 10 p.m.

. . . .

Experiment XII., January 24th.—Black cat, weighing immediately after the operation 7lbs. $5\frac{1}{2}$ oz. (3,348 grm.) Bile duct tied double and cut. February 3rd.—A brown yellow tinge now visible on conjunctivæ; most of the stitches taken out of the wound; the cat eats well. February 6th.—Jaundice increasing; wound nearly firmly united; weight 6 lbs. 10 oz.; appetite keeps good. February 7th.—Jaundice still increasing; cat is now very feeble, and when tumbled over has great difficulty in regaining its feet. February 10th.—Jaundice extremely intense. February 12th.—Cat dying; weighs 4 lbs. 7 oz. (1,995 grm.); was left alive at 5 o'clock in the evening. February 13th.—Found dead this morning at 10.

. . . .

Experiment XIII., January 11th, 1873.—A black and white cat; the bile ducts tied double and cut; this cat never became jaundiced; it was killed on February 6th, by cutting off the head.

. . . .

Experiment XIV., January 7th.—A brown yellow cat; weight 4 lbs. $15\frac{3}{4}$ oz.; bile duct tied double, but not cut. January 9th.—No jaundice, but cat very feeble. January 18th.—The conjunctivæ are now slightly jaundiced. January 22nd.—Yellowness of conjunctivæ still more marked; edges of wound in belly firmly grown together; all the stitches taken out to-day. February 3rd.—Yellowness growing less; belly wound quite healed. February 5th.—No yellowness can any longer be seen in the conjunctivæ; the belly wound can scarcely be made out, it is so firmly cicatrised; weight 4 lbs. 12 oz.; fæces dark coloured, and urine gives no green re-action with nitric acid. It was determined to kill the animal; the head was therefore cut off.

. . . .

Experiment XV., June 10th.—A tortoiseshell cat, not fully grown. The left branch of the hepatis tied once only. The cat never became jaundiced; it ate immensely, and yet it lost flesh daily. It died in the night, between June 27th and 28th.

. . . .

Experiment XVI., June 27th.—Black and white cat, well nourished, full grown. Bile duct tied double, and piece cut out. July 6th.—As the cat was now very weak, and seemed about to die, it was determined to make the diabetic puncture. The cat was therefore laid prone, a cut made through the skin, over the occipital protuberance, and the chisel applied immediately underneath this. After dividing the occipital bone the chisel was passed in a direction downwards and forwards, so as to cut the line made by joining the two auditory meatus. The chisel was pushed on until it met with the basilar bone, and was then withdrawn. Operation was over at 12.30. Before the operation the cat had languidly taken a little milk; urine passed during the operation, though highly jaundiced, gave no re-action with Trommer's test. At 2:15 urine pressed out of bladder, likewise gave no re-action with Trommer's test. July 4th.—Cat still alive; urine gave no re-action with Trommer's or Moore's test. July 7th.—The cat died in the night, between July 5th and 6th. Examined to-day at 2 o'clock. Much more peritonitis than in any other of the experiments.

. . . .

In all these cases it may be remarked that the jaundice of conjunctivæ was very close to declare itself. In none was it noticed until the tenth day after the operation; in one it did not show itself until the fourteenth. The cats were daily examined for this appearance. On the other hand, Frerichs asserts that a yellowish colour of the conjunctivæ could be noticed in sixty or seventy hours after the operation. Tiedemann, Gamelin, Leyden, and Golowin also found their dogs jaundiced on the second or third day. In Heinrich Mayer's experiments the jaundice seems to have come on later, about the same time as in my own; and it may be further noticed that he used cats, not dogs, upon which circumstances the difference between observers perhaps depends. In an old experiment by Jaunders the hepatic ducts of a dog were tied. Two hours after the dog was killed. The absorbents were found distended with a fluid of a bilious colour, and white paper dipped into the serum of blood taken from the hepatic vein gave a deeper tinge than from the jugular. I have repeated this experiment in the dog without success.

. . . .

Although the appetite in these animals remained good in most cases, yet they wasted; in one case the weight fell from 7¼lbs. to 4½ lbs. in nineteen days. The cats appeared to become weaker daily without any marked symptoms of disease.

. . . .

The cause of death in these creatures is obscure. Blondlot and many others attribute it to peritonitis. Blondlot gives a distinct cause. He says that the ligature eats through the bile duct; the bile is thus poured into the peritoneum.

. . . .

Leyden seems to think that it is the addition of the jaundice to the peritonitis which kills the animals.

. . . .

I should be far more inclined to think the cause of death to the changes which take place in the liver. The liver in these cases, as tested by iodine, contained little or no glycogen.

. . . .

Of all the functions of the liver known to us the most important is the preparation of glycogen, and this seems to pass into complete abeyance soon after ligature of the bile ducts. Glycogen is one of the most important elements of nutrition; and it is not surprising that the animals should have wasted so rapidly when the system was deprived of it. And it is to this defect in nutrition, even while the animal was taking nourishment freely, that I am inclined to attribute the fatal end.

. . . .

In [human] disease the state which most closely imitates ligature of the bile ducts is congenital obstruction of the bile ducts outside the liver. Of these cases, of which there are but few on record, there were found, in one of the more carefully examined cases, appearances which the writer calls hepatitis interstitialis; in other words, an overgrowth of the capsule of glisson. Here the same chain of events seem to take place. The change of the bile ducts into a fibrous cord influences all the connective tissue in the portal canals, and an overgrowth takes place. The nature of these changes, whether of a so-called inflammatory origin or otherwise, it is unnecessary and would be unprofitable here to discuss.—*Dr. Legg, St. Bartholomew's Hospital Reports*, Vol. IX., pp. 161–81.

Goltz ascribes the disturbance of movement produced by section of those organs, to the loss of the feeling of equilibrium . . . .

The first point investigated by Solucha was, how far is an abnormal position of the head able to disturb the feeling of equilibrium of the animal, and so to produce the abnormal movements? The author confirms the experiment of Longet that mere section of the recti capitis postici majores et minores in the dog renders the movements of the animal uncertain and insecure, the dog was unsteady on its feet, moved from side to side, kept the fore feet widely apart from each other, running was rendered difficult, &c. After five or six days the head generally assumed the normal position, and at the same time the walking became normal. In a second series of experiments the author sought to give pigeons a peculiar position of the head, without wounding important parts, a position such as occurs in section of the canals, with the beak directed upwards and the occiput towards the ground. On fixing the head to the breast in this position with a thread, the animals conducted themselves partly like those in which the horizontal as well as the vertical semicircular canals were destroyed.

. . . .

On section of one horizontal canal the animal made several lateral movements of the head, beginning from the injured side, which soon ceased. In section of the corresponding canal on the opposite side pendulum movements of the head occurred, and persisted very long. The violence of the movements increased from the beginning onwards until they reached a maximum, when the animal lost its equilibrium, fell over, executed movements de manège, &c. In a few cases the animals recovered completely, but generally after four or five days the animal was found in a corner with the peculiar position of the head above described and quite quiet, but when disturbed it resumed the pendulum movements, &c.; most of the animals died in from ten to twenty days.

. . . .

On section of all four canals, violent movement of the head, resembling a screw motion, occurred immediately, accompanied by general swinging movement of the whole body.—*Journal of Anatomy and Physiology*, 1873, p. 400.

L. Perl, in his first series of experiments (on dogs), performed seldom and large bleedings (every five or seven days, three to three and a half per cent. of the body weight at each time), in a second series more frequent and smaller bleedings (every three or four days, one to one and a half per cent.) were practised. The animals endured the operative proceedings well. The wounds healed well without fever, and only in one case did embolus of the lungs occur.

Whilst the animals of the second series, on which ten as the minimum and seventeen as the maximum of bleedings were practised, remained quite cheerful and well, and when killed, from the thirty-sixth to the thirty-seventh day, showed no signs of change in the muscles of the heart, the seven dogs of the first series, on the contrary, on which five to seven bleedings were practised, became lean, lost appetite, became sad, had partial œdema of the extremities, and died (6) with the phenomena of marasmus, within eleven weeks. With a single exception, all the animals dying after four weeks showed a very flabby heart, with a yellowish colour, and under the microscope the muscular fibres were found to have undergone extensive fatty degeneration.—*Journal of Anatomy and Physiology*, 1873, p. 407.

He ligatured the bile duct of a dog. The animal lived nineteen days, and though it continued to have a voracious appetite it emaciated visibly. The colouring matter of the bile was found four hours after the operation in large quantity in the urine, and on the second day the fæces were quite discoloured.—*Journal of Anatomy and Physiology*, 1873, p. 420.

J. W. Legg (St. Bartholomew's Hospital) operated upon cats. The animals survived the operation for varying times up to twenty days, and peritonitis when present remained local.

. . . .

The cats became emaciated and died without convulsive phenomena, and only became comatose shortly before death. With regard to the cause of death the author lays stress upon the decided diminution or absence of glycogen of the liver (tested with iodine solution).—*Journal of Anatomy and Physiology*, 1873, p. 420.

L. Seelig experimented on rabbits which had (p. 422) been allowed to hunger; diabetes was produced by Eckhard's method. The author then convinced himself that in the starving animals, after the diabetic sugar had disappeared from the urine, or occurred only in traces, corresponding to the results of Dock (the hunger period lasted three to five days, the collected urine was evacuated by pressure after it had been collected for six hours) . . . A solution of sugar (generally 20 ccm. of a 10 per cent. solution = 2 grms. sugar) was then injected into the jugular vein, in the one case into the starved animals, and in the other into the starved diabetic ones. In the former case only traces of sugar appeared in the urine when the animals had starved for

App. IV.

five, six, and seven days, somewhat more when the hunger period was shorter.—*Journal of Anatomy and Physiology*, 1873, p. 421.

A. Bidder operated on the superior epiphysial cartilage of young rabbits. The cartilage was either exposed and transfixed with needles or destroyed by section, growth of the bone was arrested either on one side or over the whole extent of the terminal surface according to the part irritated, and this effect was marked throughout the whole length of the bone as far as the distal epiphysis. Destruction of the cartilage on the fibular side was followed by growth of the opposite side, causing curvature of the bone with the convexity inwards.—*Journal of Anatomy and Physiology*, 1873, p. 425.

Dr. Burdon Sanderson delivered an address on this subject relating his first experiments as to the effect of inoculating animals with pyæmic liquids. In the autumn of 1867, he injected the purulent liquid contained in the ankle joint of a patient, who had died a few hours before with metastatic abscesses, general suppurative arthritis, and intense septicæmia, under the skin in a dog and two guinea-pigs. The two guinea-pigs died within fifteen and twenty days. Both had metastatic abscesses; in one the lungs were beset with minute nodules resembling miliary tubercles. The dog lived seven weeks, there were no secondary abscesses, but miliary tubercles of the liver and spleen. From one of the guinea-pigs, two others were inoculated; one died of pyæmic subcutaneous abscesses, without visceral disease; the other lived longer, had no abscesses, but tuberculous disease of the lungs. During the same winter other experiments were made, which seemed to show that, by the inoculation of pyæmic products, two sets of lesions might be produced; as an immediate result, metastatic abscesses, accompanied by a general typhoid state, which was often fatal; as an ulterior result, either disseminated nodules, at first hard, but afterwards becoming caseous at their centres, or interstitial in duration, both forms of lesion having their seat chiefly in the lungs, spleen, and liver, but also occurring in other viscera.—*The Doctor*, June 1872, p. 132.

Take pus—you do not want to go to decomposing vegetable or other animal fluids, you may do it with them —but take pus, and with it I could make a case of pyæmia or septicæmia according to order, by the length of time which I kept the pus before I injected it; and I know very well, in experimenting upon this subject, you may produce all degrees of the disease, and you may say that the chance of getting secondary abscesses are in direct ratio to the length of time an animal lives after it has become inoculated with the poison. When the poison is thoroughly septic, when you have that terrible substance which Dr. Burdon Sanderson has shown us how to get in the peritoneal cavity of an animal, the blood becomes so poisoned and spoilt, that it kills outright, and there is no time for the secondary effects to supervene.—*Dr. Savory, British Medical Journal*, No. 686, p, 240.

If, for example, you take perfectly fresh pus, not putrid in the least degree, pus that contains no flocculi, perfectly limpid and pure pus, and inject it into the venous system of a dog, you will get a great rise of temperature. We get shivering and malaise, and, after a certain time, the dog's recovery. You may inject a considerable quantity of pus, and you may repeat the experiment again and again, and the dog may recover. That I take to be simply pyæmia. If, on the other hand, you take pus which is no longer perfectly limpid, but a little flocculent—it need not be putrescent—which contains particles of such a size that they may stick in the vessels; and, if you inject that pus, then you get the same train of symptoms, you get abscesses, you get purulent deposits in different parts of the body, the internal viscera, and so on. In fact, you may imitate simple pyæmia and the multiple pyæmia which we get in a human subject. On the other hand, if you take putrid matter—whether vegetable or animal—for instance, if you take cabbage leaves and let them rot thoroughly in a solution, and then get this foul stinking cabbage water, if you clear away all the solid particles as far as you can, you will by these means get a train of symptoms which may be free from metastatic abscesses. You get a high temperature, you get shivering, not always, but very frequently, you get vomiting, purging, collapse, and the rapid death of the dog.—*Mr. Hulke, British Medical Journal*, No. 686, p. 238. [*See also* pp. 8 and 39.]

In the *British Medical Journal*, No. 718, and succeeding numbers, a series of 619 experiments are reported, performed by Dr. Bennett, extending over a period of four years, to show—

1. *Antagonism between Strychnia and Chloral Hydrate.*

To eighty-three rabbits and thirty-one rats were administered doses of strychnia, with the usual result of horrible torture. One of these is thus described.

Experiment 36.—On the tenth day after the former experiment one-ninetieth of a grain of strychnia was again injected into the same animal under the skin over the left loin. The animal remained quiet for five minutes, when it became restless, and moved about with a staggering gait. In two minutes more it leaped from the table, fell on its side, and had severe convulsions, with an extreme degree of opisthotonos. These convulsive attacks occurred three times, when death ensued twenty-six minutes after the administration of the poison.

2. *Antagonism between Sulphate of Atropia and Calabar Bean.*

Before commencing in this class Dr. Fraser indicated his results in the same field of experiments. Nevertheless, Dr. Bennett proceeded to operate on 112 animals, with the following shocking results.

Experiment 126.—Male rabbit, weighing 3 lbs. 8 oz. Three-fourths of a grain of extract of calabar bean dissolved in ten minims of water were injected under the skin of the back. In a minute and a half there were slight twitchings of the skin. In three minutes the breathing became very hurried, and the animal seemed to be very distressed. Saliva now accumulated profusely in the mouth. In two minutes more the animal rested on its abdomen and chest, and spread out its legs, which were stiff. It attempted to regain its natural position, but in vain. The pupils were now contracted from 7–25ths (their diameter before the experiment) to 3–25ths of an inch. Soft diffluent fæces were passed. At the end of eighteen minutes from the time of the introduction of the poison the animal was lying on its side. The respirations were much laboured. It remained in this condition for thirteen minutes more, with severe occasional muscular tremors, when it died; that is, 31 minutes after receiving the three-fourths of a grain of the extract.

3. *Antagonism between Hydrate of Chloral and Calabar Bean.*

Sixty animals in this class were tortured, their expressions being "profuse salivation," "severe tremors," "asphyxia," "very ill," "much affected," "very ill for eight hours," &c.

4. *Antagonism between Sulphate of Atropia and Meconate of Morphia.*

Notwithstanding the numerous experiments and observations which have been made on this subject, a careful investigation into the evidence which existed previously to the Committee's inquiry could not but demonstrate that nothing positive or certain had been arrived at.

One hundred and eighty-one rabbits and dogs were tortured as follows:—

Experiment 299.—Rabbit weighing 3½ lbs. Cardiac impulses 45 in ten seconds. Respirations 12 in ten seconds. Pupils measured in their transverse diameter 12–50ths of an inch. Six grains of meconate of morphia in 30 minims of water were injected subcutaneously under the skin of the back. In three minutes the animal lay on its abdomen and chest, with the hind legs extended and stiffened. The transverse diameter of the pupil was now about 11–50ths of an inch. Respirations 10 in ten seconds; cardiac impulses 42 in ten seconds. In two minutes more the animal attempted to walk, and it progressed forwards with evident difficulty, owing to the weakness of the posterior extremities. When moving a slight push was sufficient to turn the animal over on its side. In eight minutes more there were slight convulsive twitches of the muscles of the back, and the animal was now quite narcotized.

Experiment 300.—Thirty minutes after receiving the dose the respirations were reduced to six in ten seconds; the cardiac impulses fell to 38 in ten seconds, and the pupil now measured 6–50ths of an inch. The muscular twitchings had increased. After a little time there were severe spasms coming on with great suddeness, accompanied by bending backwards of the spine and pawing movements of the fore limbs. These spasms continued for nearly thirty minutes.

Experiment 307.—Twenty minutes after a dose a dog was much excited. It sat on its haunches and swayed its head from side to side. Occasionally it tried to walk, but there was evident weakness of all the limbs, more especially of the hind extremities. On placing the hand over the wall of the chest the pulsations of the heart could be distinctly seen and felt. The animal continued in this state for nearly four hours, when it began slowly to recover. It appeared to be out of health, and frequently refused food for four days after this experiment. . . . . .

A week after the preceding experiment the same dog weighed 15 lbs., and was made to take a second dose of poison. . . . .

6. *Antagonism between Tea, Coffee, Cocaine, Theine, Caffeine, and Guaranine on the one hand, and Morphia on the other.*

One hundred and seventy-six dogs, cats, rabbits, mice, and frogs were under treatment, the expressions of whose sufferings are too horrible to peruse. The following extracts are only two out of many detailed descriptions.

Experiment 430.—Six grains of theine. Cat. Death. Post-mortem examination.—Six grains of theine, dissolved in a drachm and a half of water, were injected under the skin over the back of a healthy cat weighing 4 lbs. 1 oz. In ten minutes the animal became very irritable and angry. Fifteen minutes later this excitement had increased; the animal had a watchful anxious appearance, prowled about, and when touched with a stick bit at it and growled. If any noise or motion were made it arched the back, and made a hissing noise. The legs appeared weakened, and although it could walk about it preferred sitting in a corner of the room. Its mouth and tongue were very red, and there was an abundant secretion of saliva, which constantly trickled out of its mouth. The cat defæcated and micturated several times. Forty minutes later it continued in much the same condition. Salivation was profuse. Animal suffered from tenesmus, and it had a constant straining from the bowel of a clear fluid like mucus. The limbs, especially the posterior ones, were much weakened, but the animal could still run with difficulty. It could not jump; it made attempts to do so over a bench about two feet high, but failed. The breathing was laboured and irregular. The redness of the tongue and mouth, as well as the excessive irritability of the animal, had disappeared. It was quiet, lay in a corner, stupid and drowsy. It drank freely of water. Twenty minutes later it was prostrate and lay on its side, its limbs quite helpless. It paid no attention to a pinch of the toe or a blow on the tail with a stick. It seemed, however, to be intelligent, as its eyes watched every movement of the observer, and when the hands were clapped before its face it growled. The salivation and discharge from the bowel were excessive. Pupils were contracted and the breathing was laboured. Five minutes later the cat took a series of tetanic spasms, and shortly afterwards died. . . . .

Experiment 433.—Twelve grains of theine. Rabbit. Spinal cord exposed during life.—A healthy white rabbit, weighing 2 lbs. 2 oz., was carefully fastened down on its belly. An incision was made through the skin along the upper part of the spine about two inches in length, and the vertebral column exposed. By means of bone forceps and scissors portions of the vertebræ were removed so as to expose a piece of the spinal cord about a quarter of an inch in length. On touching the posterior columns with the point of a blunt needle the animal struggled violently and uttered loud cries. . . . .

With regard to the dogs, Dr. Bennett says, "These "experiments were considered to be so unsatisfactory that "they were abandoned."

7. *The antagonism between the Extract of Calabar Bean and Strychnine.*

Twenty-four rabbits were tortured under this head.

8. *The antagonism between Bromal Hydrate and Atrophina.*

Forty rabbits were tortured under this division, Dr. Bennett closing it by saying, "The experiments were not encouraging, as all the animals died." The conclusion shows torture to 619 animals; and this is not enough, Dr. Crichton Browne says, (No. 743, *British Medical Journal*, p. 409), and he proceeds, therefore, to give picrotxine with chloral hydrate to another large number of animals, which produces in them spasms in all the muscles of the body, and causes biting of the tongue, foaming at the mouth, &c., &c.

A concise answer to the question, what is poison? really seems more difficult than ever. Men gradually habituate themselves to the use of opium, tobacco, &c., till their daily dose is sufficient to kill from two to ten of their own species. Sheep have been known to consume unwholesome plants till their flesh becomes uneatable. Goats will feed on hemlock; hedgehogs swallow almost anything; and the common toad cares little for hydrocyanic acid. Ultimately we come to the acari, which appear to enjoy a perfect immunity from the usual effects of a so-called poison; for here strychnine is only a poison in the same sense that starch would be poison to man, namely, in that it does not contain every element necessary for the reproduction of tissue.—*Lancet*, 2,015, p. 389.

Experiments on animals, already extensive and numerous, cannot be said to have advanced therapeutics much. I have seen Dr. Richardson give a pigeon enough opium to kill a strong man, and yet the bird was in no way affected; and I have heard of goats feeding on shag tobacco and rabbits on belladonna leaves without taking any harm; yet from these experiments to infer that belladonna and tobacco were innocuous to man would be a grave error. Probably calomel given to a healthy dog might cause a temporary irritation and congestive obstruction of the animal's biliary apparatus, thus showing that calomel has an action over the liver; but I cannot see my way clear to infer the action of mercury on a sick man from what we see of its action on a healthy dog.—*Dr. Thorowgood, Medical Times and Gazette*, October 5, 1872.

Dr. Marcet said if he understood rightly Dr. Harley's meaning, his interesting paper showed that small doses of arsenic continued for a long time do produce poisonous effects. A question, however, was still open to discussion, viz., how are we to account for the reported innocuous and even protective effects from the practice of arsenic-eating, which it is stated is carried on extensively in Styria? Indeed we are given to understand that in Styrian arsenic works the workmen take arsenic with a view of escaping the poisonous effects of its fumes.

. . . .

He (Dr. Marcet) observed finally that men and animals were not equally affected by poisons, a fact which it was important to bear in mind when experimenting with poisons on animals with the view of applying the results to mankind.—*Lancet*, No. 1,995, p. 499. [*See also* Langley, p. 7, Harley, p. 20, Yeo, p. 38, and Moore and Reynolds, p. 39.]

1st. If I divide the posterior column and almost the whole of the lateral column of the spinal cord, with the posterior and central parts of the grey matter in the dorsal region in a guinea-pig, I find, when the animal has become epileptic, that the irritation of the part of the face and neck which I have called epileptogenous determines reflex convulsive movements everywhere, except in the posterior limb on the side of the injury. This lack of reflex movements is not due to a paralysis of the nerves serving to voluntary movements, as, if that limb is at first a little paralysed after the operation, it soon recovers power, and has no trace of weakness by the time epileptic fits can be provoked. . . . . .

2nd. If only the posterior column and a very slight part of the grey matter, with a still slighter part of the lateral column of the spinal cord, is divided in a guinea-pig in the dorsal region, the four limbs are attacked with reflective convulsive movements when the epileptogenous zone is irritated. In this case the encephalon communicates with the posterior limb on the side of the injury for both voluntary and reflected convulsive movements.

3rd. If in another animal the lesions mentioned in the preceding experiments have been made at the same level of the cord, one on the right side the other on the left side, I find that the two sides of the face and neck acquire the epileptogenous power, and that fits can therefore be produced by the irritation of either side, but whether the right or left side be irritated, there are reflected convulsive movements only in three limbs, the posterior one on the side where the lateral column of the cord is divided remaining without the least convulsion, while the three other limbs are violently convulsed. Both lower limbs, however, remain endowed with strong voluntary movements.

4th. In animals having had a complete section of a lateral half of the spinal cord at the level of the vertebra, and having become epileptic, I have ascertained that the voluntary movements after a period of very great diminution in the posterior limb on the side of the lesion, return gradually almost to the normal condition in a variable number of months. In many guinea-pigs having recovered voluntary movements, even for a year or eighteen months, I have seen but very slight convulsions in the posterior limb on the side of the injury. Re-union of nerve-fibres serving to voluntary motor fibres can therefore take place to a very great extent in the spinal cord after having been divided, but there is hardly any re-union for the nerve fibres which in attacks of epilepsy give rise to reflected convulsive movements.—*C. E. Brown-Séquard, Lancet,* No. 2,418, p. 2.

Fortunately animals may not have any apparent diminution of either voluntary movements or sensibility after the exposure of the spinal cord to the air.—*Idem, Lancet,* No. 1,819, p. 28.

Before the operation in rabbits the most energetic pinching of the skin produces agitation but no shrieking; after the operation, on the contrary, the least pinching produces shrieking, and a much greater agitation. Sometimes the hyperæsthesia is so considerable that the least pressure upon the skin makes the animal shriek. Whether the operation is performed on the lumbar, the dorsal, or the cervical region the phenomena are always the same; that is, there is a manifest hyperæsthesia in the various parts of the body which receive their nerves from the part of the spinal cord which is behind the section. It has been so in all the animals I have operated upon, and I have already made this experiment upon animals belonging to more than 20 species.

As long as the animals live after the section of the posterior columns, hyperæsthesia continues to exist, except in the cases where re-union takes place between the two surfaces of the section; but hyperæsthesia is greater during the first week after the operation than it is after a month or many months.—*Idem, Lancet,* No. 1,819, p. 29.

In a mammal the spinal cord is laid bare at the level of the two or three last dorsal vertebræ, and a lateral half of this organ (including the posterior, the lateral, and the anterior columns, and all the grey matter, on one side) is divided transversely. The animal is left at rest for a little while, and then it is ascertained that sensibility seems to be much increased in the posterior limb on the side of the section.—*Idem, Lancet,* No. 1,820, p. 53.

To obtain a very striking result from the experiment which consists in only one section of a lateral half of the spinal cord, it is better to make it after the posterior columns have been divided. We know that after this division there is hyperæsthesia in the parts of the body which are behind the section; if, after having ascertained this fact, the section of a lateral half is completed where the posterior columns have been divided, we find that the hyperæsthesia seems to increase in the side of the second operation, while in the opposite side, not only the hyperæsthesia, but sensibility entirely disappears.

. . . .

A longitudinal section is made on the cervico-brachial enlargement of the spinal cord, so as to separate it in two lateral halves—I ascertain then that sensibility is lost in the two anterior limbs, while it remains, and even seems to be increased, in the two posterior limbs.—*Idem, Lancet,* No. 1,820, p. 54.

If the longitudinal section is more than two inches long, it is not sensitive in all its length. When there are three pairs of nerves attached to it, the one nearest to the transversal section is hardly able to give slight sensations; the next is a little more sensitive, but much less than in a normal condition; and the third is very sensitive, though not so much as the others on the same side and behind it. —*Idem, Lancet,* No. 1,820, p. 55.

If the section be made two inches higher in the dorsal region, there is, as in mammals, though less marked, an increased sensibility in the posterior limb on the side of the section, and a diminution of sensibility in the opposite limb. The loss of sensibility is never complete, showing that the decussation is not complete. The same results are obtained in reptiles.—*Idem, Lancet,* No. 1,820, p. 56.

The laying bare of the spinal cord, and its free exposition to the action of the atmosphere, instead of being a cause of loss or diminution of sensibility, as it had been said, seems to be followed by a marked increase of sensibility in the parts of the body which are behind the place where the cord is exposed.

The laying bare of the spinal cord even in mammals is very rarely followed, after a number of days, by any kind of accidents (meningitis, myelites, &c.) producing a diminution of sensibility . . . . . .

Deep injuries to the posterior columns of the spinal cord are always followed by a degree of hyperæsthesia greater than after the laying bare of the nervous centres, hyperæsthesia which appears in all the parts of the body behind the place injured.

. . . .

All the parts of the encephalon which are situated in its posterior or superior side are like the posterior columns of the spinal cord in this respect—that a marked degree of hyperæsthesia always follows a transverse section upon any of them. If a complete transverse section is made upon any part of the restiform bodies, sensibility becomes very much increased in every part of the trunk and limbs. Hyperæsthesia is also but at a less degree, one of the results of a transversal incission in the cerebellum, in the processus cerebelli ad testes, and in the tubercula quadrigemina. . . . . Every small portion of a transverse section of the conducting zone, in a lateral half of the spinal cord, contains conductors—of sensitive impressions coming from all the points of the body, on the opposite side, which are behind the place of this small portion.—*Idem, Lancet,* No, 1,823, p. 137.

I have found that a convulsive affection very much resembling epilepsy may be produced in animals. A few weeks after certain injuries to the spinal cord, in the dorsal or lumbar region, especially in guinea-pigs, fits appear spontaneously several times a day, or, at least, once every two or three days. But the most interesting point is, that it is possible to produce a fit when we choose, by simply pinching a part of the skin. These fits consist in clonic convulsions of almost all the muscles of the head, the trunk, and the limbs, except those muscles which are paralysed . . . .

I have ascertained that one part only of the skin has the power of producing the fit, and this part is that which covers the angle of the lower jaw, and extends from thence to the eye, the ear, and nearly to the shoulder. It is only the skin that has the power of generating the fit, as even the three nerves that send filaments to this part of the skin can be irritated without the occurrence of convulsions. When the spinal cord has been injured only on the right side, it is only on that side that the skin of a part of the face and neck has the power of inducing fits, et vice versâ when the injury exists on the left side. If the two sides of the cord are injured, the two sides of the face can produce fits.—*Idem, Lancet,* No. 1,840, p. 571.

If we take two living animals of the same species and decapitate them by a section passing in one of them on the nib of the calamus scriptorius and in the other on the fourth or fifth cervical vertebra and cutting also in both the principal nerves of the neck and avoiding the section of the carotids, we often find that the first one has no convulsions, or in other words no agony, while the second almost always has very violent convulsions in the four limbs and in the trunk . . .

More than ten years ago I found that certain animals may live for many weeks, and in more recent researches, for eight months, after the extirpation of the whole medulla oblongata.

In these animals all the functions of organic life except pulmonary respiration continue without any apparent alteration, showing that these functions do not depend upon the medulla oblongata as some physiologists have thought. The persistence of life in these animals was possible on account of the cutaneous respiration, but in animals in which the skin absorbs but a small amount of oxygen, such as birds and mammals, death is said to be always rapid after the extirpation of the medulla oblongata, even when care is taken to avoid the influence of the operation upon the heart. It seems, therefore, that the medulla oblongata is an organ absolutely necessary to respiratory movements . . . . .

It is known that the only two appearances of proof that the medulla oblongata is the only centre of respiratory movements, or, in other words, the only source (direct or reflex) of these movements in the cerebro-spinal axis, are, 1st, that a transversal section of the lower part of medulla oblongata causes a sudden cessation of respiration; 2nd, that when transversal sections are made on the encephalon, from its front to its back, taking away layer after layer, it is said that it is only after the greater part of the medulla oblongata has been taken away that respiration is destroyed. As regards the first of these two assertions, we have already shown the objections against it, objections which are also very good against the second assertion. But we must say a few words more of this second assertion. When, after a series of transversal sections of the encephalon, we have reached the medulla oblongata, just above the upper roots of the par vagum, we find that respiration continues almost normal. If now we cut away the part of the medulla giving origin to this pair of nerves, we find in most cases that respiration is suddenly stopped . .

In weak animals after many parts of the encephalon have been taken away, the whole of the medulla oblongata and of the pons Varolii remaining, respiration sometimes continues normal, but it suddenly stops after a small part of the pons is removed. . . . .

The stronger an animal is the more parts of its encephalon can be taken away before we destroy respiration.

. . . .

In the strongest animals death occurs in a few hours, and from insufficiency of respiration, after the ablation of the encephalon except the whole of the medulla oblongata, and so it often is with anencephalic monsters. . .

A series of experiments on pigeons has given me the following results; with the spinal cord alone respiration continues a few minutes, with the spinal cord and the part of the oblong medulla giving origin to the principal excitors of respiration, the vagi, this function continues many hours (the longest duration we have seen is thirteen hours), if there is also a great part of the base of the encephalon left respiration continues longer but I have never seen it last more than a day and a half, . .

It seems indeed wonderful to see animals sometimes after a slight puncture of some part of the encephalon with the point of a needle, turn round, just like a horse in a circus, or roll over and over for hours and sometimes for days, with but short interruptions. . . .

Parts producing turning or rolling after an injury on the right side.

Turning or rolling by the right side.	Turning or rolling by the left side.
1. Anterior part of the optic thalamus (Schiff).	1. Posterior part of the optic thalamus (Schiff).
2. The hind parts of the crus cerebri (Schiff).	2. Some parts of the crus cerebri near the optic thalamus (Brown-Séquard).
3. The tubercula quadrigemina (Flourens).	3. Anterior and superior parts of the pons Varolii.
4. Posterior part of the processus cerebelli ad pontem (Magendie).	4. Anterior part of the processus cerebelli ad pontem (Lafargue).
5. Place of insertion of the auditory and of the facial nerves (Brown-Séquard and Martin-Magron).	5. Place of insertion of the glosso pharyngeal nerve (Brown-Séquard).
6. Neighbourhood of the insertion of the lower roots of the par vagum (Brown-Séquard).	6. Spinal cord, near oblong medulla (Brown-Séquard).

While rotation takes place it is easy to ascertain, 1st, that it is not its production by contractions resembling those of voluntary movements which causes the rolling or the turning; 2nd, that some muscles are in a state of tonic contraction; 3rd, that the trunk and neck of the animal are bent by a spasmodic action on the side of turning if it has a circus movement, and that it is bent like a corkscrew, as much as the bones allow, in cases of rolling; 4th, that sensibility and volition may remain, and there are frequent efforts to resist the tendency to turn or roll. . . .

And now, to add to the strangeness of the fact, in this last case the muscles remain contracted sometimes for hours, sometimes for days and weeks.—*Idem, Lancet*, No. 1,841, pp. 599, 600, 601.

M. Flourens has found that the section of the semicircular canals, in certain animals, is followed by a strange disorder of movements, and sometimes by a rotation (circus movement). I have ascertained that the phenomena observed in these experiments do not depend on the section of these canals, as this operation may not cause these phenomena, but that they are the results of an irritation of the auditory nerve, from the drawing upon it by the membranous semicircular canals at the time we divide them. In frogs and in mammals the direct irritation of the auditory nerve is followed by the most interesting phenomena. It is well known that in frogs the peripheric extremity of this nerve is enclosed in a bag containing carbonate of lime; as soon as this bag is laid bare and slightly touched, and still more if it be punctured with a needle or a bistonry, the anterior limb, on the opposite side, is thrown into a state of slight convulsion, and kept almost constantly in a spasmodic pronation, and almost at every attempt to move forwards the animal turns round on the side injured. As long as it lives (many days, or even many months) these phenomena may be observed, although not quite so marked as immediately after the injury or after the first 24 hours. In mammals the least puncture of the auditory nerve causes rolling, just as after the irritation of the processus cerebelli ad pontem; violent convulsions then occur in the eyes, the face, and many muscles of the neck and chest. The doctrine that the nerves of the higher senses are not endowed with general sensibility (*i.e.*, are not able to cause pain) seems not to be true with regard to the acoustic nerve; at least, the signs of pain given after an irritation of this pretended nerve are often as great as those observed after an irritation of the trunk of the trigeminal nerve.—*Idem, Lancet*, No. 1,842, p. 625.

I have now to speak of the condition of animal heat in cases of alteration of the spinal cord and the encephalon. The following conclusions may be drawn from a great many facts bearing on the subject: 1st, that usually anæsthesia is accompanied by a diminution of temperature: 2nd, that hyperæsthesia almost always co-exists with increased temperature; 3rd, that in paralysis, without either a notable hyperæsthesia or anæsthesia, the temperature is nearly normal. I must remark that the state of heat of a part is due to the amount of blood, the degree of heat of this fluid, the exposure of the part to the influence of the temperature of the surrounding medium, and the temperature of this medium.—*Idem, Lancet*, No. 1,843, p. 652.

Professor Brown-Séquard is continuing with indefatigable labour the series of his valuable researches and experiments upon the physiological pathology of the nervous system. His communications to the Academy of Medicine have formed the most marked features of the recent sittings of this learned society. As you will doubtless give full attention to these researches when they shall have been published in extenso, I shall only mention a few points thereof so as to keep you au courant of everything that crops up here at the very moment of the event. My letters must be photographs of the passing occurrences of the day. M. Brown-Séquard's most recent researches bear upon the consequences produced by certain lessons of the corpora restiformia and the sciatic nerve in guinea-pigs. According to the illustrious experimenter, when the sciatic nerve is severed in guinea-pigs on exciting a certain determinate part of the face which he names le zone epileptogene epileptiform phenomena are produced. Excitement of no other portion of the face can induce an attack of epilepsy. But in order that the phenomena may take place, it is necessary that the excitement should be produced on the side corresponding to the limb where the nerve has been divided. M. Brown-Séquard showed two guinea-pigs to the Academy and reproduced his experiments before the assembly. M. Colin, one of the members, mentioned that he had often performed the division of the sciatic nerve without being able to induce epileptiform attacks. M. Brown-Séquard's experiments on the restiform bodies are equally interesting and curious. One of the results of injury to the corpora is the production of hæmorrhage under the skin of the ear. Hitherto certain kinds of hæmorrhage had been observed as the result of injury to the nervous system, for instance hæmorrhage of the kidneys in diseases of the spinal cord and hæmorrhage of the intestinal tube in diseases of the brain. But the fact now illustrated is remarkable on account of its constant occurrence. Another result is the production of dry gangrene of the ear, which, according to the experimenter, is not the consequence of paralysis produced by the section of the restiform bodies. M. Brown-Séquard exhibited a guinea-pig showing this kind of gangrene. At the last meeting of the Academy he again adverted to the subject, and stated that the precise point of the restiform body which he excited in order to produce hæmorrhage and sphacelus was the nib of the calamus scriptorius. Some particulars he added tended to show that this situation was really the one which he excited in his experiments, for instance, the paralysis of the tongue and anæsthesia of the lips—the animal could not hold the food which was introduced into its mouth. It was a well known fact that the hypoglassal nerve and fifth pair take their origin in the neighbourhood of the calamus scriptorius. M. Brown-Séquard concluded by pointing out the strict analogy which exists in a great number of cases between the phenomena determined experimentally in animals and those which are observed clinically in man. On account of the extreme interest of these experiments M. Bouillaud has requested M. Brown-Séquard to repeat his experiments before a certain number of the members, which has been assented to.—*Lancet*, No. 2,380, p. 514.

In the course of some recent experiments on the establishment of artificial epilepsy in guinea-pigs, Dr. C. Westphal has been over the same ground as that explored by M. Brown-Séquard, and fully corroborates the results at which the latter observer arrived. He adds, however, some new and interesting facts. Thus, he found that if one or two slight blows on the side of the head are given to a guinea-pig they are sufficient to bring on an epileptiform attack, after which the animal again recovers its liveliness, or it remains heavy for some time and then exhibits a kind of rotatory movement, like those shown by Schiff to occur in rabbits after lesion of the crus cerebri.

. . . .

If the animal survives the blows, a similar epileptigenic zone is created as in the guinea-pig treated on M. Brown-Séquard's method by lesion of the medulla oblongata at certain points or section of the sciatic; and as in these last cases, the zone is near the angle of the lower jaw. Before the zone is well established, and four weeks are usually required for this purpose, the animals betray the presence of some irritation at this part by frequently scratching it. After it is established slight punching will induce tonic and clonic spasms though the sensibility of the skin is here diminished. The rapidity with which the zone can be established may be increased by striking the animal's head on successive days, and the excitability of the zone endures for a period varying from six weeks to six months. The condition is hereditary. M. Westphal set himself to ascertain the nature of the changes induced by the blow or blows. That the condition is not produced by any alteration in the integuments is shown by the circumstance that the fits occur when the exposed skull is struck.—*Lancet*, No. 2,528, p. 195.

Dr. Brown-Séquard has with great kindness related to me his more recent researches, and shown me the interesting little animal upon which he is now experimenting. I have therefore the pleasure of being able to speak of them de visu, and of adding some interesting details of the note which I sent you two weeks ago. If you remember I then mentioned that the professor's recent researches were upon some of the effects of section of the sciatic nerve and injury to the corpora restiformia in guinea-pigs. A great number of the animals were shown to me in which the sciatic nerve had been severed, and in all the zone epileptogéne did exist. I mean one single spot by exciting which the fit was immediately produced. Pinch wherever you like independently of that situation, and though the animal will not like it, and will scream more or less, there is nothing abnormal, but as soon as you excite the particular spot it goes into a fit. In this situation, which may be easily circumscribed, extending from the ear to the eye round below the jaw, and backwards to the shoulder-blade, there seems to be an obvious impairment of nutrition, the hair is much less abundant, parasitical animals are found there, &c., and besides sensibility is considerably diminished. The fits produced are quite similar to those brought on by section of the lateral half of the spinal cord.

Dr. Brown-Séquard showed me some animals in which the paw of the limb where the sciatic nerve had been divided was more or less injured. This, he observed, was not a spontaneous injury, which must be attributed, as had been thought to the division of the nerve. The dragging of the paralysed limb produced a slight abrasion, and as soon as there was a drop of blood, the little animal set to gnawing the insensible extremity. It is also the case with rabbits. There must be, however, a drop of blood to excite the voracity of the animals. In some of them two of the claws of the feet, the two outer ones, animated by the great sciatic nerve, which alone is severed, had fallen off, while the remaining claw and middle one, animated by the little sciatic nerve, was unimpaired. By wrapping up the limb in a bag as soon as section of the sciatic nerve is performed the experimenter prevents any injury occurring.

With regard to his other series of experiments, those in the corpora restiformia, the professor showed me a great number of guinea-pigs in which I could trace the effects of injury to that particular part of the nervous system. The ears of several guinea-pigs showed the appearances of dry grangrene. In some of the animals half of the ears had already fallen. The aspect produced by the solution of continuity along the edge of the ear is quite distinct from that of a bite. In a bite the little portion of the ear seems cleanly cut off, whereas in dry gangrene it appears to have crumbled off. I have noticed the remains of two or three hæmorrhagic clots which had formed on the ear.

To conclude, I may just mention that Dr. Brown-Séquard was much surprised when some of the French journals stated that he had neglected to note the occasional occurrence of hæmorrhage in the ears of insane people. The fact is that the very object of the illustrious experimenter in mentioning the phenomena which he observed in Guinea-pigs was to show that the hæmorrhagic clot observed on the ears of mad patients, and concerning the etiology of which there is still much discussion, may be due to purely internal nervous causes, and not to external violence, his chief aim in every one of these experiments being their application to the pathology and therapeutics of the human species.—*Lancet*, No. 2,382, p. 586.

Nothnagel employs a new method for the determination of the functions of the brain. His observations are made mostly on rabbits. An incision is made in the scalp; the skull is perforated with a needle. Through the canal thus formed in the bone a very small drop of a concentrated solution of chromic acid is injected by means of a hypodermic syringe with a very slender nozzle. The scalp wound is then united by suture, and the animal does not seem to be affected, except with regard to the functional derangement incidental to the lesion. Generally they survive the operation two or three weeks, and die from causes which Nothnagel cannot explain, no constitutional symptoms being developed.—*The Doctor*, November 1st, 1873, pp. 214 and 215.

Professor Nothnagel of Freiburg, contributes a paper to the last of Vichow's Archiv·Band, lvii. (Heft. 2, p. 184), containing an account of a series of researches he has recently made in Heidenhaur's laboratory upon the functions of the brain. With a few exceptions his experiments were made upon rabbits placed thoroughly under the influence of woorara. He acknowledges that dogs are better subjects for experiment, whilst their more convoluted brain resembles more closely than the rabbit that of man.

On the other hand, rabbits can be obtained in any number, and they are not difficult to keep. The plan adopted by Professor Nothnagel, was suggested to him by Professor Heidenham and is somewhat peculiar. It consists in drilling a small hole through the cranium, through which the cannula of a subcutaneous injection syringe is inserted and plunged to a greater or less depth into the brain. A minute quantity, perhaps not amounting to more than quarter or half an ordinary drop, of a concentrated solution of chromic acid is then injected and the effects watched. The pain must be slight, as the animal often remains passive till the sutures required to close the wound are inserted. It is also obvious that in this mode of procedure bleeding and those alterations which might result from evaporation and exposure to cold are avoided. When the acid was injected directly into the ventricles, death took place in from ten to thirty minutes, the pulse becoming very slow and great dyspnœa setting in, soon followed by increased action of the heart and convulsions. . . .

Similar experiments upon dogs, the acid being injected into the outer extremity of the gyrus postfrontalis, were attended with analogous results. . . . .

When the animals lived for a fortnight or more they appeared to recover completely. . . . .

Injection into the lenticular nucleus constantly produced the above described deviation of the limbs. Injection into the nucleus caudatus appeared for the first few minutes to be without effect, but soon the animal began to leap forward, the leaps succeeding one another faster and faster till, after some minutes, it dropped exhausted upon its side, the limbs continuing to move rapidly.—*Lancet*, No. 2,601, p. 18.

Nothnagel has continued his researches on this subject, still using the injection of chromic acid. When only one lenticular body was operated on the results were the following:—Deviation of the leg of the opposite side (right) towards the middle line and that of the same side (left) outwards, a lateral curvature of the spine with the convexity turned towards the opposite side (right) and at the same time a moderate cypposis. The animal could, however, execute all voluntary movements.

A different state of things occurred when lotn. micleilenticular is that operated on. In 26 cases the author succeeded with the operation, and the results in all cases coincided.

. . . .

The spinal column was sometimes straight, sometimes cypnotic, but never curved laterally. The ears were erect and never laid backwards upon the neck. Respiration and action of the heart normal. If the fore limbs were carefully extended so that the animal did not lose its equilibrium, and though the feet might be placed in a very unnatural position, as were the neck, they were not drawn back, as always occurs in the normal animal. Slight pinching of the tail, which a normal animal would notice, was followed by withdrawal of the foot from the unnatural position, and the animal appeared as if it would spring, but with one spring the movement came to an end, and the animal became motionless as before. The same thing could be repeated over and over again. In some cases the animal sprung four, six, or even sixteen times. The animal sat without making any attempt at spontaneous movement, and if not disturbed until death occurred, just like an animal from which the cerebral hemisphere had been removed. Nor did the animals eat of their own accord. Most of the animals died on the second or third day, but *six* lived till the seventeenth day and were very emaciated.—*Stirling, Journal of Anatomy and Physiology*, November 1874, p. 210.

On October 25th he divided the right hypoglossal nerve in a rabbit, and took out a piece about a quarter of an inch in length. Immediately after the operation, and during the whole time that the animal was under observation, the tongue was strongly protruded to the right side. On November the 27th the rabbit was killed.—*Mr. Clarke, Doctor*, January 1st, 1872, p. 24.

Dr. Milne Edwards also endeavoured to substitute the carbonates of iron, manganese, and magnesia respectively for that of lime in bones by an artificial diet. This diet having reduced the pigeons subjected to experiment to utter emaciation they were killed; the bones were extremely brittle and thin, but only traces of magnesia and iron were discovered in two and none in the third. So thus the composition of bone does not appear susceptible of alteration by substitution; and Dr. Milne Edwards concludes that bone is a compound of two primordial substances, viz., phosphate of lime and osseine, the immediate principle of bone. Rather a lame conclusion this after all.—*Dr. Milne Edwards, Lancet*, No. 1,977, p. 69.

Another, and a very droll discovery, made by the same Professor (who, by the way, should be called to order by some member of the Society for the Prevention of Cruelty to Animals) is that the testicle of one frog may be engrafted into the body of another animal of the same species, so that one "froggy" may "go a-wooing" with the testicles of another froggy, and not at all à ses propres frais; this seems a "leetle" too much. His last experiment is far more intelligible than the preceding, in part, at least. He says, "If you transplant into the abdomen (under the skin) of a female frog, a few days before the laying of her eggs, a frog's testicle, such is the attraction between this body and the eggs that ulceration of the abdominal muscles takes place, the male and female elements coming into contact, and so violently that the frog dies." This last result is, I confess, the only portion of the whole paper which I can conveniently credit.—*Lancet, No.* 1,931, p. 224.

One frog died in twelve hours, another was killed, and the third, after remaining on its back in a tetanic condition for ten days, recovered.—*Dr. Harvey, Lancet*, No. 2,053, p. 7.

C.

EVIDENCE OF DESIGN TO TEACH STUDENTS BY VIVISECTION.

[The numerous handbooks published for students would alone provide this evidence; but professors have spoken out their thoughts freely, and these are reported as well as the contents of handbooks. Foreign handbooks are extensively used in England, but these have not been quoted from. The volume published by Drs. Burdon-Sanderson, Klein, Foster, and Brunton, necessarily appears in this division. Its experiments might have been classed under (A.) and (B.), but the tendency of its teaching would not have been seen so well by such an arrangement. Consequently, a large number of experiments appear under this head. That the object of the editor and his co-adjutors was to induce young persons to perform experiments on their own account and without adequate surveillance is manifest throughout the work, by the supply of elementary knowledge and elaborate data. Not only are the names and quantities of necessary chemicals given, but the most careful description is provided in letter-press and plates of implements for holding animals during their struggles, so that a novice may learn at home without a teacher. Besides, the editor's preface states, that the book is "intended for beginners," and that "difficult and complicated" experiments consequently have been omitted; and that of Dr. Foster allures the student by assurances of inexpensive as well as easy manipulation, for it avers that the experiments "may for the most part be conducted on frogs, may be repeated any number of times without difficulty or expense, and so serve usefully as a means of training students in physiological study and inquiry."

Very seldom indeed is the student told to anæsthetise, and then only during an operation. It cannot be alleged that "beginners" know when to narcotise, and when not; but if they do then the few directions to use chloral, etc. are unnecessary. No doubt should have been left on this point in a handbook designed "for beginners." Besides, where will students find cautions against the infliction of unnecessary pain, and wanton experimentation? On the contrary, the student is encouraged to repeat the torture "any number of times." These facts are significant.]

Advance of Physiology.—*Nature*, No. 204, p. 456–7.

Presumption of students.—*Dr. Scoffern, Belgravia*, April 1867, p. 221.

Experiments during lecture.—*Lancet*, No. 2,471, p. 3.
Dr. Rutherford, Lancet, No. 2,476, p. 185.

Pflüger discovered a curious fact regarding the stimulation of a motor nerve, and the effect which it produces on a muscle. He found that when he stimulated with equal force the sciatic nerve of a frog at one time near the gastrocnemius and at another time at a distance from the muscle, in the latter case a more powerful impression was produced on the muscle. We shall perform the experiment.

I dissect out the sciatic nerve of a frog, sever it from the vertebral column, but leave it connected with the leg.—*Dr. Rutherford, Lancet*, No. 2,483, p. 438.

I shall illustrate what I have been saying by some experiments. We have here a white rabbit . . . . I now cut down upon the cervical sympathetic nerve. Let us take that on the right side for convenience. I expose the nerve about the middle of the neck. I separate it from the superior cardiac branch of the vagus, a smaller nerve which lies close beside the sympathetic, and I put a fine silk ligature round the sympathetic, and tie it firmly round the nerve. The effect of this is to paralyse the nerve as thoroughly as if the nerve were divided. Now compare the two ears and the two pupils again. The vessels in the right ear are much larger than those in the left ear. The right ear is in consequence distinctly redder than the left You see also that the right pupil is smaller than the left one. I shall now divide the nerve immediately below the ligatured point and then irritate the nerve just above the ligature. In an experiment of this sort we call this part of the divided nerve its "upper" end; the end of the nerve which lies below the point of section is called the "lower" end. Watch the vessels of the right ear while I faradise (stimulate with faradic or induced electricity) the upper end of the nerve. You see that they contract, and the ear in consequence becomes blanched. We shall wait for a few moments until the irritation passes off. Now look at the right pupil while I irritate the upper end of the nerve again. You see that it dilates enormously under the influence of the irritation. We have seen then that on paralysing the cervical sympathetic blood vessels of the ear on that same side dilate and the pupil on the same side contracts, and that on stimulating the upper or cranial end of the divided nerve precisely the converse takes place in both parts. We therefore conclude that this nerve contains fibres whose function is to cause the vessels of the ear to contract and the pupil to dilate, and that these fibres convey their influence up the neck. As I want to keep the experiment as simple as possible, I shall not stimulate the lower end of this nerve at present. I cut down the phrenic, and I open the abdomen in order that you may see the diaphragm. You see that at intervals both sides of the diaphragm are drawn downwards. I divide the right phrenic nerve in the neck. Now look at the right side of the diaphragm. It remains quite loose and flabby when the left side is drawn down instead of being tightly drawn down with it as before. I shall now irritate the lower end of the nerve. Watch the diaphragm. You see that the right half is drawn violently downwards during the irritation, and that the flabby state returns when I stop the irritation of the nerve. We conclude that the right phrenic nerve contains motor fibres for the right half of the diaphragm, and that these influences pass through the nerve down the neck.—*Idem, Lancet*, No. 2,483, p. 439.

Under this head some general questions regarding sensory nerves were discussed, and the mode of estimating the amount of ordinary sensibility in a part was demonstrated.

. . . .

I take another frog. In this case I open the cranium and remove the brain and medulla oblongata.—*Idem, Lancet*, No. 2,487, p. 565.

He was aware that there were some who entertained the idea that vivisection was not necessary when it had for its object the mere demonstration for educational purposes of facts already known.

Those who held this doctrine appeared to him to forget that physiology was an experimental science, and that no right conception of the subject could be obtained unless the student was shown the experiments that were necessary for the demonstration of certain facts.

. . . .

Now he maintained that this definite and critical knowledge regarding the bodily organism could not be attained unless their students were shown experiments on living animals.—*Speech of Professor Rutherford, the British Medical Association, Edinburgh*, 1875.—*Scotsman.*

In recent years the teaching of physiology had made a great stride in this country. Laboratories duly appointed had been and were being organised; and the method of physiological instruction had in most instances passed from the mere prelection illustrated by diagrams to an experimental exposition of the subject. In his student days the latter element was wanting, and at this moment there was distinct danger of a return to something like that miserable mode of instruction in consequence of the fanatical clamour of a number of persons, excited, it must be admitted, by one or two members of their own profession.

. . . .

Physiology was an experimental science, and that no right conception of the subject could be obtained unless the student was shown the experiments that were necessary for the demonstration of certain facts.

. . . .

Had not every teacher repeatedly observed the altogether different mental attitude which students assumed the moment he passed from mere description to a demonstration of phenomena? He far more forcibly arrested their attention, and far more deeply imprinted on their minds the facts he would bring home to them.

. . . .

Definite and critical knowledge regarding the bodily organism could not be attained unless their students were shown experiments on living animals, and he held that those authorities who seemed to be of opinion that this method of tuition might be dispensed with, were entirely overlooking the vast importance, not only to the student himself, but to the whole race, of an experimental manner of laying the foundation of a knowledge of the institutes of medicine.

. . . .

It was not necessary for a sound physiological education that their students should be shown all the experiments that were needed to demonstrate physiological truths; they probably did enough if they showed experiments on the cardinal points of physiology; and he averred that all the experiments on the higher animals that were really required for the purpose of education, could be performed with the aid of narcotics. Seeing that this was so, why should it be that some had become convinced that, in consequence of the present inflamed state of the popular mind on the subject of vivisection, the right education of medical students must be abandoned? The popular mind had been abused by inaccurate and misleading statements regarding both their motives and their actions. He maintained that a great and deplorable error was committed when the unreasonable clamour of the anti-vivisectionists was met in the spirit of compromise instead of the spirit of stern resistance. He believed that the unfortunate Vivisection Bill which was laid on the table of Parliament conferred a dignity on the policy of the anti-vivisectionists which, but for that Bill, it would probably never have possessed. It was true that there had been a withdrawal of that singular Bill, according to which they were to have been fined fifty pounds, or to have been sent to prison for two months, if they had dared to show to their students any experiments, even upon a narcotised animal. But the effect of the Bill was not effaced; the increased boldness which it had given to the pretensions of the anti-vivisectionists was only too evident. All that they could now hope was that the good sense of the Legislature would in the end prevail, and that it would do nothing to hamper the education of medical men.

The learned professor went on to explain, with the help of numerous diagrams, the result of a series of experiments he had made in reference to the action of certain drugs on the biliary secretion of the dog.—*Dr. Rutherford, Lancet*, No. 2,711, pp. 238–9.

On the art of experimenting.—*Professor Brown-Séquard, Lancet*, No. 2,380, p. 514.

Students should spend time in the physiological laboratory.—*Dr. Ross, British Medical Journal*, No. 738, p. 238.

Dr. Burrows, Lancet, No. 2,371, p. 208.

Elementary lessons in physiology.—*Professor Huxley, Saturday Review*, 1/10/74.

Experiments performed at the Physiological Laboratory, University of Edinburgh.

W. B. A. Scott, M.D., Edin.

[Letter to the *Echo*.]

J. Burdon-Sanderson's Lectures delivered in the Physiological Laboratory of University College.

In 1863 the lamented v. Bezold published his well-known researches on the nervous system of the heart. Among a number of other less important discoveries, he showed for the first time the nature and extent of the influence exercised by the brain and spinal cord on the circulation of the blood. He found that when, in a curarised rabbit or dog, the spinal cord is severed from the brain, the arterial pressure sinks very considerably, while at the same time the number and extent of the contractions of the heart are diminished; and that if, on the other hand, the upper end of the divided spinal cord is irritated below the point of section, the arterial pressure rises to its original level and the heart to its previous activity.

The leading experiment is as follows:—Two centigrammes of curare, dissolved in a cubic centimetre of water, are injected below the skin, and immediately after artificial respiration is begun. This dose is sufficient, as was first shown by v. Bezold himself, to paralyse the extremities so completely that neither stimulation of the cord nor of any muscular nerve produces, the slightest contraction of voluntary muscles, while, as we shall see on another occasion, it is not sufficient to interfere with the action of the heart. Respiration of course ceases, but it is maintained, as I have said, mechanically, the means employed for the purpose being a pair of bellows the tube of which communicates with a cannula adapted to the trachea of the animal.

The membrane between the atlas and the occipital bone having been previously exposed and one of the carotid arteries connected with the manometer of the kymograph, observations are taken of the arterial pressure and of the frequency of the pulse. This done the spinal cord is divided at the atlas. Immediately the rate of pulsation is diminished, say from 140 to 100, and after a few seconds the arterial pressure sinks, say from three or four inches to one or two. Needles are then inserted into the spinal cord, one at the upper edge of the axis, both of which are connected with the secondary coil of Duboi's induction apparatus. At once the heart beats more frequently and vigorously and the mercurial column attains its former level.

The next step in the experiment is the destruction of the cerebro-spinal cardiac nerves. These nerves, as you know, reach the heart or leave it either through the vagi or the sympathetic.

The destruction of the nerves is best effected with the galvanic cautery, the action of which is more certain and more easily controlled than any other agent which could be employed. It answers the purpose so completely that in careful subsequent dissection it is found that every nerve is served. As soon as the destruction of the nerves is effected the spinal cord is again excited, great care being taken that the strength of the current shall be the same as in the previous observation.

There are, however, in these and other respects considerable differences in the results observed in different animals the conditions of which have not yet been determined.*

Upon another dog, under partial anæsthesia, he divided with a fine curved scalpel the corpus striatum and optic thalamus on one side, the corpus callosum having previously been cut through. The electrodes were then placed on the convolutions above and behind the sylvian fissure. Contraction resulted, when the current was strong, not only in the fore leg of the opposite side, but also in the hind leg. In another experiment he removed the whole cerebral masses above the fous varolii, and applied the electrodes to the surface of the section. Muscular contractions resulted, limited to the fore limbs, right and left.—*Lancet*, No. 2,630, p. 136.

Handbook Physiological Laboratory,

[Some of the following experiments are quoted not to show extreme torture, but regardlessness to suffering as well as the minute character of directions given, to bring them within the capacity of young people.]

Page 1.—Take the newt out of the water, dry the tail, cut off its end. If no blood comes, squeeze the organ from the root towards the tip until a drop is obtained.

Page 25.—To study the forms of the various cells of the separate layers we may obtain a thin shred from the surface of the tongue or gums of a mammal by energetically scraping it with a scalpel.

Page 26.—Finally, if we have scraped very energetically with the scalpel, we meet with cells corresponding to the deepest layers. . . . A frog is held by an assistant, its nictitating drawn down, and from the anterior corneal surface a thin layer is scraped with a lancet-shaped or a cataract knife.

Page 34.—It is not difficult to remove those structures [network of elastic fibres] even from the living animal. The easiest way is to place the vocal cord for a few minutes in dilute acetic acid, and then to scrape off the epithelium with a lancet-shaped needle, a process which is much facilitated by the previous steeping in the acid.

Page 35.—A frog is held by an assistant in such a way that the bulbus oculi is tense. The membrana nictitans is then drawn back, and the bulb penetrated with a cataract knife, just as in the operation for cataract, at the limbus conjunctivæ next the inner canthus. The point of the knife is advanced until it approaches the limbus of the opposite side, without puncturing it, and is then carried outwards and upwards, so as to form a flap, consisting of the upper half of the cornea. The extreme edge of the flap must then be seized with the forceps, while the lower half of the cornea is cut away with the aid of scissors curved in the direction of their edge. The cornea is next transferred to a drop of humor aqueus (previously obtained by puncturing the opposite eye), and spread out on the glass slide with anterior surface uppermost.

Page 38.—Preparations are obtained by stripping off shreds of a cornea (of a rabbit or frog). . . .

The centre of the cornea of a frog, which is held by an assistant in the manner previously described is firmly cauterized with a pointed stick of lunar caustic. One or two drops of salt solution are then allowed to flow over the cornea to decompose the excess of nitrate of silver. About an hour after the cauterization the cornea is excised in the manner directed in p. 35. . . . . .

It consists in first scraping the cornea of a living frog or small mammal with a sharp cataract knife so as to remove the epithelium completely. After a little practice, and provided the bulb is properly fixed by an assistant, it is not difficult to perform this operation without injuring the substance of the cornea, Thereupon the caustic is two or three times lightly rubbed over the whole surface, after which the eye is washed with saline solution, and the animal is left to itself for twenty or thirty minutes. The cornea is then excised.

Page 44.—If in a rabbit the skin and subcutaneous tissue are divided over the inner (anterior) third of the infraorbital edge, and the thin membrane which stretches over the infraorbital fossa is severed, it is easy to remove, along with the glandula infraorbitalis, a gelatinous hyaline mass.

. . . .

If the tail of a very young rat is amputated, and the tip torn asunder from the cut end, a great number of isolated lengths of tendon are obtained.

Page 54.—The leg of a water-beetle (hydrophilus) is torn out and its horny covering removed.

Page 60.—One of the hind legs of a tadpole is amputated at the thigh. The animal is then replaced in water. After forty-eight hours the loosened muscular fibres hang from the stump in long pencils. These are cut off close to the surface of the stump with sharp scissors. . .

Page 78.—In a living or recently killed rabbit the cornea is excised close to the limbus.

. . . .

A silk thread having been passed through the centre of the cornea of rana esculenta and brought out again at the sclerotic ring, the two ends are knotted together. After the thread has remained from five to eight hours the cornea is excised.

Page 97.—In a large frog secured on its back the abdominal vein is carefully exposed under a dissecting lens, in its course up the middle line of the anterior wall of the belly. A ligature is passed round the distal end of the prepared part and tightened.

Page 98.—The external jugular of the animal is then exposed by a sufficient incision, and cleared of the surrounding tissue with the aid of dissecting forceps.

Page 108.—A snip is made in the right side of the belly. . . . . The incision is then continued upwards and downwards in such directions as to avoid bleeding. . . . The muscles are divided in the same vertical line. . . . . The intestine and mesentery are drawn out carefully.

Page 109.—The animal must be cararised as before . . . . . the tongue drawn out by the cornua, around which a thread must be secured . . . . . to pins.

Page 113.—In a large or middle-sized rabbit which has been kept from sixteen to twenty hours without food, ten cubic centimeters of a warm five per cent. solution of Prussian blue are injected into the abdominal cavity . . . . . After three hours and a half the animal is bled to death by opening the carotid artery, or killed by strangling.

Pages 158 to 162.—The inflammatory changes of the epithelial elements of the cornea may be studied by abrading the epithelium over a limited surface in several frogs, and examining the organ at various periods after the injury. . . . . . . After two or three days sections may be made by shaving off a portion of the mucous membrane. . . . In the blood vessels the inflammatory changes may be studied by cauterizing the external surface of any superficial vein (*e.g.*, the external jugular or femoral), or even by simply ligaturing the vessel. Three or four days after the injury the vessel is excised. . . . The best method is to pass a needle into the knee-joint of a rabbit in such a way that it penetrates into the tibia. A few days after sections are made of the fresh cartilage, and stained in gold. . . . Germination of the cells of bone may be induced in the long bones of mammalia by passing a red-hot needle as deeply as possible into a bone previously freed of the soft parts covering it, and then cauterizing the hole with a pointed stick of nitrate of silver, or by violent fracture. After a week or more the bone is excised. . . . Inflammation of the tissue of the liver may be induced by passing a needle into the organ. Twenty-four to forty-eight hours after the injury the animal must be killed. . . . The cornea may be cauterized at the centre to such a depth as almost to perforate it, or a thread may be drawn through it, entering at the centre and passing out through the sclerotic beyond the margin, the ends of which are then tied. . . . . To study the successive stages of the process half a dozen corneas should be prepared in this way at a time, which can then be excised after eight, twelve, eighteen, twenty-four, thirty-six, and forty-eight hours. The best preparations are obtained from rana esculenta during the summer months, from eight to twenty-four hours after the introduction of a silk thread as above described. . . . Inflammation is produced in one eye by cauterization, and then twenty-four hours after a portion of the cornea of the other eye is excised, spread out carefully, and lodged between the membrana nictitans and the cornea of the injured eye. The membrana nictitans is then drawn up and secured by two or three ligatures to the skin. After twenty-four hours more the sac is opened and the cornea taken out. . . . . . . The mucous membrane covering the large lymphatic sac of the under surface is snipped off with curved scissors. The observation is necessarily tedious, often lasting for forty-eight hours. It is therefore desirable to replace the tongue in the mouth for a time after each examination. . . . . In a curarized tadpole the required degree of irritation can be produced either by simply pencilling the surface or by allowing a drop of ammonia to fall on it from a capillary pipette, or, finally, by piercing it with a needle. The research must be continued often for many hours.

---

* This beautifully simple experiment we owe to Dr. Stricker, with whom I had the pleasure of repeating it here very frequently last summer.—*Medical Times, No.* 1,094, *pages* 683 *and* 684.

Page 166.—Several frogs are then selected, in each of which the pericardium is exposed, and divided as directed in § 46, and a snip made in the ventricle with fine scissors.

Page 174.—In a rabbit two small incisions are made across the course of the external jugular vein (*see* § 48), one near the clavicle, the other near the origin of the vessel, great care being taken not to go deeper than is necessary, in order to see the vessel through the fascia. A small needle is then passed under the vein, near the proximal incision, in a direction at right angles to that of its axis, and corresponding to that of the incision, but deeper. A second needle is then laid in the course of the incision, and drawn tightly towards the first by a ligature at either end, by which means the blood-current is entirely arrested, while the coats of the vein are absolutely protected from injury. A second pair of needles is then inserted at the distal incision, and secured in a similar manner so as to shut in the blood with which the vein becomes distended after the tightening of the first ligature. After the lapse of a couple of days the ligatured portion of the vein is exposed at some part of its course, and punctured with a glass pipette, by means of which the blood is withdrawn from it by suction in a perfectly liquid state. . . . . . The arterial trunks leading from the heart of a frog or tortoise are first tied, and then (as soon as the heart has become distended) the venous trunks. The heart full of blood is removed from the body. . . . . The pericardium of a frog is then exposed and divided, and a snip made in the ventricle with absolutely clean scissors.

Page 176.—A frog having been secured in the usual way (*see* § 46) in the prone position, the heart is exposed, and the right aorta ligatured. A clip is then placed on the left aorta at its origin from the bulb.

Page 212.—The animal having been secured on Czermak's rabbit board, and the fur clipped, the skin is pinched up between the finger and thumb on either side of the upper end of the trachea so as to form a horizontal fold, which an assistant divides vertically. . . . . The opening having been enlarged with the aid of a second pair of blunt forceps, the sterno-mastoid is slightly drawn aside, so as to bring the artery with its three accompanying nerves, the vagus, the depressor, and the sympathetic, into view. The sheath having been opened the artery is raised on a blunt hook, and easily cleared from its attachments to a distance of three-quarters of an inch in either direction . . . When kept closed by the adjusting screw, seize upon the head of a cat or rabbit in such a manner as to hold it firmly without inflicting the slightest injury. The neck of the animal rests on a cylindrical cushion, covered with waterproof cloth, and the rest of the body on a mattress of similar material. Along the edges of the board there are convenient attachments for the extremities.

Page 229.—The excellency of this method lies in the fact that the animal can be kept under observations, without the use of any narcotising drug, for a long time in a perfectly natural condition. The frog is used both in the larval and adult state. To observe the circulation in the tail of the tadpole, the animal is placed in a moderately strong solution of curare, care being taken to remove it before it is completely paralysed—the moment, in short, that its motions became sluggish. It is also possible to secure it, without the aid of curare, in a holder of construction similar to that of the instrument I have just described—a method which has this great advantage, that the animal is in a more normal condition; for even when curare is given with the greatest care, the action of the heart is weakened by it.

. . . .

There are three transparent parts of the frog—the mesentery, the web, and the tongue—each of which has its special advantages for the purposes of study. For a first view of the relation between arteries, capillaries, veins, and lymphatics, the mesentery is superior to either of the other two. The frog must be placed under the influence of curare, the dose of which for the ordinary specimens of rana temporaria, is about $\frac{1}{2000}$th of a grain. . . . .

The solution of curare is prepared by weighing out five milligrammes of the substance, and rubbing it up in a glass mortar with a little alcohol. . . .

The proper quantity of water—that is, sufficient to make up ten cubic centimeters—is then added, and a straw-coloured, nearly limpid liquid is obtained, a single drop of which is a sufficient close. It is injected under the skin of the back with an ordinary subcutaneous syringe, and answers best when the effect does not manifest itself for some time after the injection.

Page 230.—The observation may be continued without material change for many hours.

Page 233.—All being now ready, a frog, previously slightly curarized, is fixed on the table in the supine position. The integument is divided over the sternum in the middle line, and the anterior wall of the upper part of the visceral cavity removed, so as to expose the pericardium, great care being taken not to injure the abdominal vein, or any other large vessel. The ventricle is then opened, and the cannula passed through the opening into the bulb, and secured by a ligature. This done, the heart is drawn upwards.

Page 235.—Two frogs are slightly curarized, and placed side by side on the same board in the supine position. In both the heart and great vessels are exposed as in the preceding section. . . . . . The brain and spinal cord are destroyed in one of the frogs by inserting a strong needle into the spinal canal immediately below the occipital bone, and then passing it upwards and downwards. [The other frog is left sensitive].

Page 236.—Two frogs are suspended side by side, one of which has been pithed in the manner above described. In both the heart is exposed and the ventricle cut across.

Page 237.—A frog having been curarized just sufficiently to paralyse its voluntary muscles. . . . . All being now ready, the integument is opened along the middle line of the back of the neck, and the occipital bone perforated in the middle line with a fine awl close to its posterior margin. . . . . The frog is then laid, back downwards on the board, in such a position that one of the needles enters the cranium through the hole in the occipital bone, the other the spinal canal. . . . . . Finally, the heart is exposed as before.

Page 238.—The dose of curare must be very small, and should therefore be given an hour or two before the observation is made. One at least of the electrodes must be inserted within the cranium; for if both are below the occipital bone the effect is uncertain. . . . . The integument is divided in the middle line from the pomum adami downwards, as directed in section 1. On drawing the edge of the incision to either side, the external jugular vein is readily seen as it crosses the sterno-mastoid. It is then carefully cleared of the platysma fibres and fascia which cover it, and of its sheath to the extent of an inch or more, with the aid of two pairs of blunt forceps. . . The animal being under the influence of curare its voluntary muscles are paralysed.

Page 240.—The cannulæ having been placed in the trachea and external jugular vein, and the apparatus for artificial respiration being in order, three-tenths of a centimeter of a one per cent. solution of curare is injected. . . . . . With the help of this needle three ligatures are passed underneath the muscles which stretch vertically on either side of the spine of the atlas. . . . . . The ligatures having been tightened and the muscles divided in the middle line . . . . . all that is necessary is to divide carefully first the skin, and then the fascia which covers it. . . . . . To observe the effect of vascular contraction on the heart that organ must be exposed. In a curarized animal this can be effected without interfering materially with the vital functions. Ligatures of fine copper wire having been passed with the aid of a curved needle around the 3rd, 4th, 5th, and 6th cartilages, close to the left edge of the sternum, and a second vertical series of ligatures around the corresponding ribs at a sufficient distance outwards, the portion of the thoracic wall which lies between the two series can be removed without hæmorrhage. It is then seen that after section of the cord the heart is flaccid and empty, and that its cavities fill and its action becomes vigorous when the vascular contraction caused by excitation of the peripheral end forces the blood forwards so as to fill the right auricle.

Page 242.—For this purpose the occipital bone must be perforated with a small trephine in the middle line between the occipital protuberance and the occipital spine. By this opening a thin-bladed knife is introduced in the middle plane with its edge outwards, by which the medulla is divided, first on one side, then on the other. . . . The currents employed must be feeble when the nerves are excited by the direct application of the electrodes to the sensory nerves, but strong when it is intended to excite their cutaneous or mucous endings. The periods of excitation should always be very short. The experiment may be varied as follows :— A frog having been carefully curarized . . . . the points of the excitor are placed upon the tongue, the mouth being kept open for the purpose.

Page 243.—A frog having been curarized the integument is divided along the outer and posterior aspect of the thigh in a line which corresponds in direction with the slender biceps muscle, or rather with the groove between the muscular mass which covers the front of the femur (triceps femoris) and the bulky semi-membranosus. The sciatic nerve, accompanied by the sciatic artery and vein, lies immediately underneath the biceps, between it and the semi-membranosus. In order to separate it from the vessels it is best to bring it into view by raising the biceps on a blunt hook. . . . . . . The nerve is divided a little above the knee and the central end laid on the copper points.

Page 245.—The animal having been curarized the apparatus for artificial respiration is connected with the trachea. . . . . . The great auricular nerve is then carefully exposed, separated from the surrounding parts with the aid of two pairs of blunt forceps, and divided. . . . . If care is taken neither to prolong the excitation unduly, nor to use too strong currents, the re-action may be witnessed a great number of times in the same animal.

Page 265.—The heart of a frog having been exposed in the usual way, a stout glass rod is introduced into the æsophagus. All the other organs may now be removed in the manner directed in § 63, care being taken to avoid interfering with the venæ cavæ.

Page 269.—A frog having been slightly curarized. . . . . . the sternum is then divided in the middle line, and the two halves of the wall of the chest drawn to either side, so as to expose the pericardium and lungs, while a stout glass rod is passed down the æsophagus.

Page 271.—The preliminary steps of the experiment are those described in § 34. Loose ligatures having been placed round both vagi, and a kymographic observation made to determine the normal arterial pressure and frequency of the pulse, both nerves are divided simultaneously. [Of a dog.] . . . . . . The contractions of the heart become so frequent that the oscillations can no longer be followed by the eye, all that can be distinguished being a vibratile movement of the column. On exciting the peripheral end of either vagus the same effects are produced as in the rabbit.

Page 272.—A frog is secured in the supine position. The pleuro-peritonæal cavity is then opened, and the intestines and other viscera are removed, great care being taken not to injure the mesentery or the vessels and nerves which it contains.

Page 273.—To show this a frog is secured on its back, the pleuro-peritonæal cavity opened, and the heart exposed as before. The surface of the intestine is then smartly tapped. . . . . If the ganglionic cord is then divided on each side opposite the junction of the two aortæ, and the experiment repeated, no effect is produced, Another frog is prepared in the same way, with the exception that both vagi are divided. . . . . . . The same thing happens if, instead of dividing the vagi, the cord is divided immediately below the medulla. . . . . In a rabbit the trachea is connected with the apparatus for artificial respiration, and the vagi are exposed in the neck. Thereupon the spinal cord is divided immediately below the medulla oblongata. . . . . In the dog, section of the cord generally diminishes the frequency of the pulse. There is no such effect in the rabbit.

Page 278.—In a curarized rabbit, in which artificial respiration is maintained in the usual way, an incision is made in the middle line, extending from the upper third of the sternum to the upper end of the trachea. The external jugular vein of one side is then brought into view, tied in two places, and divided between the ligatures. The sterno-mastoid muscle is also divided between ligatures; a strong threaded aneurism needle is thrust under the sterno-clavicular ligament, and the upper fibres of the pectoral muscles; these with the ligament are divided between ligatures, and the cut ends drawn aside. . . . . The superficial parts having been exposed by two lines of incision, one of which is in the middle line, while the other extends from it on either side in the direction of the sterno-clavicular ligament, and the jugular vein having been divided between ligatures, the next step is to find the pneumogastric nerve at the upper part of the wound, and free it from the surrounding tissues. . . . . To find it, the most certain method is to seek for the trunk of the sympathetic in the upper part of the space, where it lies concealed behind the carotid artery, and then to trace it down to the ganglion. All this having been accomplished without bleeding, there is no difficulty in passing a ligature round the ganglion, so that at any desired moment it may be extirpated. . . . . . . Both ganglia having been thus prepared with as little loss of time as possible, the sympathetic and vagus are divided. . . . . . . The medulla oblongata is then divided.

Page 285.—Two frogs having been slightly curarized are prepared thus: the heart having been exposed lege artis, a small opening is made in the skin in the occipital region. In one of the frogs the brain and spinal cord are completely destroyed by passing a needle upwards and downwards from the occipital region, and then both are hung vertically on a board, side by side, looking in the same direction. [Sensibility is retained in the other.] . . . . The discharge of sanguineous liquid goes on for one or two hours, and if during the progress of the experiment, the vasomotor centre is stimulated reflexly by exciting a sensory nerve or the surface of the skin, it is seen that the rate of flow is at once augmented, but becomes less after the cessation of the excitation than it was before.

Page 289.—This may be demonstrated graphically by puncturing the anterior wall of the visceral cavity, and introducing through the puncture a cannula in such a way that it communicates with the cavity of one lung.

Page 293.—A rabbit having been secured on the rabbit support, the skin is perforated with a scalpel close to the left edge of the middle of the sternum. This having been done, the point of the tube is easily passed into the right pleura by pushing it in a horizontal direction behind the sternum, with its point against the posterior (*i.e.*, as the animal is placed the under) surface of the thoracic wall.

Page 297.—The student must avail himself of the excessive and infrequent respirations of animals in which both vagi have been divided.

Page 298.—The best view of the movements is obtained by dividing the hyothyroid membrane. The skin having been carefully divided in the middle line, lege artis, the membrane must be exposed with the aid of two pairs of forceps.

Page 306.—A ligature is passed round each nerve a little below the cricoid cartilage.

Page 308.—Rabbits in which both vagi have been divided commonly die before the end of the first day. Dogs live longer, often two or three days.

Page 309.—By far the best method is to introduce into the peritonæal cavity, by means of a small opening in the linea alba, close to the ensiform cartilage, a small flat bag of india-rubber of such size that it can be conveniently slipped between the diaphragm and liver.

Page 312.—Excitation of the superior laryngeal nerve.— The experimental investigation of the superior laryngeal is much more difficult than that of the trunk of the vagus, partly because the nerve is difficult to reach and runs a short course, partly because it is very slender. To expose it in the rabbit, an incision should be made extending from the side of the trachea at the level of its first and second rings to the hollow between the angle of the jaw and the larynx. After severing the skin in the usual way, the fascia which extends forwards from the edge of the sterno-mastoid muscle must be carefully broken through with the aid of two pairs of dissecting forceps, so as to expose the parts seen in fig. 227. The space is divided into two by the artery, the direction of which coincides exactly with that of the original incision. Near its lower end the artery gives off its thyroid branch. At the top the space is limited by the tendon of the stylohyoid muscle, and the posterior cornu of the hyoid bone. Immediately below the muscle is the trunk of the ninth nerve which arches forwards towards the tongue. The descending branch of that nerve passes downwards and forwards to reach the muscles which cover the front of the trachea, giving communicating branches to the cervical plexus, and a branch which arches forwards over the artery to gain the muscles which draw the larynx upwards. Before proceeding to expose the deeper nerves, it is well, in order to avoid confusion, to remove the descendens noni; the next step is to draw the larynx well to the side opposite to that chosen for the incision, so as to widen the space between it and the carotid artery. This done, the exposure of the superior laryngeal becomes easy. Its exact position is indicated in the figure; its course is much twisted so as to allow of the up-and-down movements of the larynx. In preparing it, no cutting instruments must be used. It must be freed from the surrounding structures with the aid of two pairs of forceps, any veins in the way having been divided between two ligatures.

Care must be taken, however, to leave a certain quantity of cellular tissue about it to serve as a kind of protective sheath, and make it somewhat less liable to get dry. The nerve having been prepared, a ligature must be tied round it as near as possible to the thyrohyoid membrane, after which it must be divided beyond. In the dog or cat the mode of preparation is very much the same as in the rabbit. In the cat, the comparative thickness of the nerve facilitates the manipulation.

In exciting the superior laryngeal, the great source of difficulty is the proximity of the vagus and the consequent liability of that nerve to be acted on by the induced current in a unipolar way. This accident which is of course fatal to the success of the investigation, the functions of the two nerves being opposite, is to be avoided, not by the use of complicated arrangements for the insulation of the nerve, but by placing it in such a way on the ordinary copper points that the part acted on is separated by a considerable air space from the surrounding tissues. Before beginning the excitation, the secondary coil must be shifted to a distance from the primary, and the primary current divided by means of Helmholtz's side wire into two branches, one of which only passes through the breaker. The other is led directly from the battery to the coil, so that the primary current is never entirely opened. In this way the opening induction shock, which, in the ordinary arrangement of the induction apparatus, possesses a much greater tension than that of the closing shock, is so reduced that the two become nearly equal to each other.*

Consequently, as the risk of unipolar action varies with the maximum intensity of the current, it is very much diminished by this contrivance, so much so, indeed, that if care is taken to prepare the nerve properly, even moderately strong currents may be used without any effects referable to unipolar excitation of the vagus manifesting themselves. Excitation of the central end of the superior laryngeal produces, according to the strength of the current used, either diminution of frequency of the respiratory movements or complete relaxation of the muscles of inspiration. The most advantageous way of judging of its effect on the diaphragm, is to expose that muscle in the way directed in § 91. It is there seen that that muscle becomes absolutely flaccid during excitation of the nerve, and it is drawn up by the elastic contraction of the lungs, so as to assume its highest possible position. When the excitation is discontinued, the relaxation either gives way to natural breathing or is immediately succeeded by one or two vigorous inspirations. If the current is so feeble that it merely diminishes the frequency of the respirations, without arresting them, the tracings show that there is no diminution of the duration of the inspiratory acts, and that the slowing is entirely due to a prolongation of the intervals, *i.e.*, of the periods during which the diaphragm remains in the position assumed by it at the close of ordinary expiration. To record the effects graphically, any of the methods recommended in the preceding paragraphs may be used. If the method described in § 99 is employed, a tracing is obtained which exactly resembles fig. 255.

The tracing fig. 256 † was drawn by inserting a bag between the diaphragm and the liver.

Page 316.—The experiment by which it is proved that the respiratory phases of arterial pressure and pulse frequency are independent of the thoracic movement consists in curarizing a dog by the injection into the venous system of a dose of solution of curare only just sufficient to paralyse the respiratory muscles.

Page 319.—For this purpose a cannula must be fixed air-tight in the trachea. . . . . .
Excessive respiratory movements in which at first the expansive efforts of the thoracic muscles, afterwards the expulsive efforts of the muscles of the abdominal wall are most violent. . . . . . .
Towards the close of the first minute the animal becomes convulsed. These convulsions must be attentively studied, because they are the type by comparison with which all other convulsions of the same order are described or defined. . . . . . Afterwards the contractions of the proper expiratory muscles are accompanied by more or less irregular spasms of the muscles of the limbs, particularly of the flexors. Early in the second minute the convulsions cease, often suddenly; simultaneously with their cessation, the expiratory efforts become indistinguishable, . . . and the animal lies in a state of tranquillity, which contrasts in the most striking way with the storm which preceded it. . . . . In these spasms which accompany the final gasps of an asphyxiated animal, the head is thrown back, the trunk straightened or arched backwards, and the limbs are extended, while the mouth gapes and the nostrils dilate.

Page 321. The respiratory movements, at first natural, are gradually exaggerated, both as regards their extent and frequency. . . . . . Towards the end of the period, as in the former case, the expiratory movements gain in vigour, both absolutely and relatively to those of inspiration, so that each inspiratory act is immediately followed by a sudden tightening of the anterior abdominal wall, accompanied by convulsive twitchings of the limbs. . . . . . Suddenly the violent expulsive efforts cease and the inspiratory movements assume the character already described, consisting in spasmodic contractions of the diaphragm, accompanied by gasping movements of the head and neck.

Page 322.—During the convulsive struggle, and particularly towards its close, the heart enlarges to something like the double of its former dimensions,—this enlargement being due to the lengthening of the diastolic interval, and to the quantity of blood contained in the great veins, which in fact are so distended that if cut into they spirt like arteries. . . . . The effect of these changes on the arterial pressure can be best studied in a curarized animal.

Page 363.—Poison a frog completely with curare . . . Dissect out carefully one of the large muscles of the thigh . . Cut away with it the piece of the pelvis to which its origin is attached.

Page 395.—Introduce between the skin of the back of a strong frog a drop or two of a solution of curare. . . . In a short time the frog will be found perfectly motionless, with its respiration arrested, but its heart still beating.

Lay bare the sciatic nerve in the thigh, slip under it a pair of electrodes connected with an induction coil and stimulate the nerve with an interrupted current. . .
If the animal has been thoroughly poisoned, no contractions whatever in the muscles of the leg will follow upon the application of a stimulus. . . . If contractions do make their appearance, the poisoning is not complete; and the student must wait or inject a further quantity of the poison. . . . Lay bare any of the muscles of the leg and apply the electrodes directly to them. Contractions will be manifest upon the application of a very slight stimulus. . . .
In a strong frog make an incision through the skin between the ilium and coccyx along the line *k.m.* fig. 266. Cut cautiously through the ileo-coccygeal muscle until the peritoneal cavity is reached. The three nerves which go to form the sciatic nerve will come into view when the sides of the wound are held apart. Very cautiously, by means of a small aneurism needle, pass a thread under these nerves, putting it under from the outside and bringing it out again on the median side. . . . Repeat the same process on the other side, passing the same thread under the nerves of that side too, but putting it in at the median side and bringing it out at the side. . . .
Tie the thread very tightly round the abdomen so as to check entirely the flow of blood to the lower limbs. All this may be done under a slight dose of chloroform . . . Pinching or otherwise stimulating either hind foot may produce movements in either one or both hind limbs, but in no other part of the body.

Pinching or otherwise stimulating the skin of the head fore limbs or trunk above the ligature may produce movements in the hind limbs, but in no other part of the body.

These facts are intelligible only on the hypothesis that the curare has destroyed (or suspended) the irritability of the motor nerves in that part of the body to which, by means of the blood current, it has had access, but has not destroyed the irritability of the sensory nerves or of the central nervous system. Pinching the skin of the fore limb gave rise to an afferent nervous impulse, which, either by volition or by reflex action, gave rise in turn to efferent impulses, which were unable to manifest themselves through the poisoned motor nerves of the fore limbs and trunk, but found vent through the unpoisoned motor nerves of the hind limbs. In order to bring out these results well, the dose of poison must not be more than sufficient to poison the motor nerves. . . . . In a fresh strong frog lay bare the sciatic nerve on one side, . . place a ligature under it, near where it divides into two branches, and tie the ligature tightly round the leg above the knee. The circulation of the lower right leg will thus be completely arrested; but, inasmuch as the nerve is not included in the ligature, there will be complete nervous connection betweeen the right lower leg and the rest of the body. Poison with curare . . . . . In a fresh strong frog dissect out a gastrocnemius (or any other single muscle), dividing both insertion and origin, and ligaturing its blood vessels, thus leaving it connected with the rest of the body by its nerve only. Poison the frog with curare.

---

* For a fuller explanation of the difference between the two induced currents and of the effect of Helmholtz's modification, see Rosenthal, "Electricitätslehre," p. 120.

† The tracing fig. 256, shows that during the whole period of excitation the diaphragm remained motionless in the position of expiration, with the exception that at gradually lengthening intervals it executed momentary contractions. When after the cessation of excitation the respiratory movements were resumed, they were slower but more extensive than before.

Page 400. The results are most clear and distinct when the organs of consciousness are intact, and the ordinary tokens of sensation are used to determine whether the impulses caused by stimulation of the peripheral terminations reach the conscious central nervous system or not. But the facts may also be readily shown in the absence of the brain, when reflex action is taken as a proof of a centripetal impulse having reached the spinal cord. In the former case, the frog should be placed under chloroform during the laying bare of the roots. In the latter the medulla should be previously divided in the neck. The frog being placed on its belly, make an incision in the middle line of the back, from the upper end of coccyx to the level of the fore limbs. Having hooked back the flaps of skin, carry the median incision down to the spines of the vertebræ and dissect away the longitudinal muscles on either side, so as to lay bare the bony arches, and then hook back the muscles on either side, or cut them away altogether.

With a small but strong blunt pointed pair of scissors cut through, on either side, the arch of the last (eighth) vertebra (be careful not to thrust the scissors in too deep), and remove the piece so loosened. Proceed then to the next arch above and so remove, three arches. The roots of the nerves will be seen lying in the spinal canal. Snip away the remains of the arches, on each side, until the last three (or four) roots are quite clear, being very careful not to touch the nerves with the scissors. . . . The frog being completely at rest, draw the ligature tight, observing the frog all the while. If the animal be in good condition, some movements will be visible in some parts of the body as evidence either of sensibility or reflex action. Now cut the nerve between the ligature and the cord: some movement will probably be again witnessed.

Lift the peripheral stump of the nerve carefully up by means of the ligature, and slip it upon the curved shielded electrodes which may be held in the hand, or, better, fixed on a movable stand. To prevent any escape of the current, slip a fragment of india-rubber sheeting beneath the nerve and electrodes, so as to isolate these from the cord and from the rest of the nerves. Pass a moderately strong interrupted current through the electrodes. If there be no escape of the current the animal will not move in the slightest.

Repeat the observation with the nerve root next above (the 8th), with this difference: place the ligature as near as possible to the walls of the spinal canal; divide the nerve between the ligature and the wall, and place the central instead of the peripheral stump on the electrodes.

Ligature and section as before produce movements. A very moderate current applied to the central stump will produce very considerable movements in various parts of the body, *i.e.* signs of sensation or reflex action, as the case may be.

Ligature or section of the posterior roots of spinal nerves produces movements in various parts of the body. Stimulation of the peripheral stump produces no movement whatever; stimulation of the central stump produces considerable movements.

These movements, be they simple reflex actions or more complicated voluntary movements set going by conscious sensations, are evidences of centripetal sensor impulses, excited in the posterior sensory roots.

Page 402.—In a fresh strong frog lay bare the roots of the spinal nerves and divide the posterior roots of the 7th, 8th, 9th, and 10th nerves on the right side and the corresponding anterior roots on the left side.

The left leg will remain motionless, being simply dragged along by the rest of the body, but never moving of itself. (If the brain has been previously destroyed or separated from the spinal cord, the right leg will be drawn up as usual, but not the left leg.)

Page 403.—Recurrent sensibility. This is never witnessed in the frog. It can only be shown in the higher animals, the cat or dog being best adapted for the purpose. The method adopted is very similar to the above, the arches of one or two vertebræ being carefully sawn through or cut through with the bone forceps, and the exposed roots being very carefully freed from the connective tissue surrounding them. If the animal be strong and have thoroughly recovered from the chloroform and from the operation, irritation of the peripheral stump of the anterior root causes not only contractions in the muscles supplied by the nerve, but also movements in other parts of the body indicative of pain or sensations. On dividing the mixed trunk at some little distance from the junction of the roots, the contractions of the muscles supplied by the nerve cease, but the general signs of pain or of sensation still remain.

Page 411.—In a frog with divided medulla, ligature the hind limbs, leaving the nerves free as directed in chap. 31 for curare, and afterwards inject a small dose of strychnia.

Demonstration of the functions of the chorda tympani and sympathetic fibres of the submaxillary gland in the dog. The animal was placed under the influence of the chloroform, when no less than 15 different dissections were made to obtain a fistulous opening. After which the author says, p. 473, "The animal must previously be " allowed to recover from chloroform, or no increase [of " saliva] will be observed."

Page 474.—After division of both nerves the secretion of the submaxillary gland, which in the normal state only goes on when the gland is directly or reflexly excited, becomes constant and abundant. This effect does not occur until some time after section, and may last for days or weeks. A similar condition of the gland is produced by the introduction of curare into the blood which is supplied to the gland by its arteries.

Page 477.—Give the dog a hearty meal, so as to distend its stomach completely, and make it lie close against the intestinal walls. Anæsthetise the animal by chloroform, taking care that the vapour is mixed with a sufficient proportion of air. Lay it on its back on the table, shave off the hair from the epigastric and hypochondriac regions, and remove the hairs carefully by a sponge, so as to prevent the risk of their getting into the peritoneal cavity. Make a vertical incision, about an inch and a half to one side of the linea alba, preferably the left, and parallel to it, extending downwards from the lower edge of the costal cartilages to a distance somewhat less than the diameter of the flange of the cannula. Divide the muscles parallel to the course of their fibres. Tie every bleeding point before opening the peritoneum, so that no blood shall get into its cavity. Open the peritoneum on a director. Lay hold of the stomach with a pair of artery forceps at a point where there are not many vessels, and draw it forwards. Pass two threads with a curved needle into the gastric walls, at a distance from each other about equal to the diameter of the tube of the cannula, and bring them out again at a similar distance from the points where they were introduced. Make an incision into the gastric walls, between the two threads, rather shorter than the diameter of the tube of the cannula. Put a pair of forceps, with the blades together, into the incision, and then dilate it by separating the blades till it is large enough to allow the cannula to be introduced. Push the cannula into the stomach up to its outer plate. Tie the stomach to it by the threads, and then pass their ends through the edges of the wound in the abdominal wall in such a way as to fasten the stomach to it, and at the same time to keep the cut edges in apposition. No other suture is required. Leave the cannula uncorked for at least half an hour after the operation is finished, for when the dog recovers from the chloroform it will vomit, and if the cannula be corked the fluid contents of the stomach are apt to be forced passed the side of the cannula into the abdominal cavity. Feed the dog on milk for one or two days, and if the operation be performed in winter, keep it in a place warmed night and day. The day after the operation the edges of the wound will be much swollen, but the swelling will subside in a day or two. After the wound has begun to heal, the cicatrix may thicken, and the outer plate of the cannula begin to press too much on the skin, so that it ulcerates. If this should occur, the cannula must be lengthened by screwing the two flanges further apart. The cannula may be closed by an india-rubber stopper, or by a cork. If the dog tears out the cork with his teeth, soak it in decoction of colocynth, or put a little phosphoric acid on its outer end. In order to collect the juice, let the animal fast for several hours, so that its stomach may be quite empty, but not for more than a day, as the mucus membrane would become covered with a thick coating of mucus. Let an assistant pat the dog and keep him quiet, with draw the cork from the cannula, and tickle the inside of the stomach with a feather tied to a glass rod. Put a small beaker underneath, so that the end of the rod rests on its bottom: the gastric juice will flow into it down the sides of the rod.

Page 494.—This may be still better seen in the cat. . . . . To show these facts, a cat must be placed under chloroform, after which both vagi are prepared and the stomach exposed. If now the animal having partially recovered from the anæsthetic, the stomach is seized between the thumb and forefinger, and subjected to traction in the direction of its length, slight but unequivocal signs of uneasiness are perceived. The vagi are then divided.

Page 499.—To get the urine, hold the rabbit over a large beaker, compress the abdomen with the palm of one hand, and press with the thumb of the other on the bladder just above the pubes, pushing it well down into the pelvis.

Page 505.—Chloroform the animal, and secure it on the rabbit-support. Make an incision from an inch to an inch and a quarter long through the abdominal parietes in the linea alba from the xiphoid process downwards. The pyloric end of the stomach is thus exposed. Pull gently on the stomach until the duodenum is brought into view. The part corresponding to the superior transverse part in man forms a loop with its convexity directed towards the diaphragm, into the top of which convexity the ductus choledochus enters. Tie the duct in this situation, then seize the gall bladder with a pair of forceps. It is always full, and cannot be missed if the forceps are passed immediately under the edge of the costal cartilages. Make a small incision into the gall bladder, introduce a cannula and tie it in. The diameter of the cannula should be from two to three centimeters, and the end to be inserted should have a projecting rim. This can be made very readily by heating the end of a piece of glass tubing of the proper size, and pressing it, while hot, against a flat piece of iron. Sew up the wound, leaving the free end of the cannula outside. The bile in guinea-pigs is secreted in very large quantities, being as much as 7·3 grammes in an hour per kilogramme of body weight. It contains a very small proportion of solids, about 1·3 per cent. When the bile duct is tied the guinea-pigs die in less than 24 hours, but when it is not tied they will live for a week.

Page 515.—Place a rabbit in the prone position on Czermaks' rabbit-support, and fix the head to the upright at the side. Feel for the occipital protuberance, and make an incision over it, about half an inch long. Fix the point of the chisel in the middle line of the skull, just behind the protuberance, and bore through the bone, moving the handle of the instrument from side to side, in order to assist its passage, but not pressing with too great a force. When the skull has been penetrated, push the chisel downwards and forwards through the cerebellum in such a direction as to cross a line joining the two auditory meatus until it is stopped by the basilar process, and then gently withdraw it. Remove some of the urine in half an hour or an hour afterwards, and test it for sugar.

Page 516.—Bernard prefers for the purpose large dogs, sheep dogs being best, as they are less subject to peritonitis than others. Five or six hours before the operation the animal should get a large meal of bread and meat. The operation, which must be performed as quickly as possible, consists in laying the dog on its left side, and making an incision 5 centimeters long in the right hypochondrium. . . . . . The duodenum lies opposite the wound. As soon as it is exposed it is drawn out. . . . . . . The duct is opened with scissors, and a plain silver cannula, about 5 millimeters in diameter and 10 or 12 centimeters long, pushed into it up to its first division.

Page 517.—For permanent fistulæ, Ludwig and Bernstein choose small dogs, as in them the duodenum is more easily reached from the middle line, and is not drawn so far from its natural position by the fistula as in larger animals. The dog must be kept fasting on the day of the operation, as the pancreatic vessels are full during digestion, and bleed easily. Narcotize the animal by injecting opium into the tibial vein, and open the abdomen by an incision about two centimeters long in the linea alba, midway between the ensiform cartilage and the umbilicus. The duodenum is then searched for and drawn out of the wound along with the attached pancreas, and a thread looped round the duct. Instead of then putting in a cannula a piece of lead wire is inserted into the duct, so that one end of it passes into the intestine, and the other into the gland to a considerable distance. The middle part of it is twisted together and projects through the wound. Owing to the T shape thus given to the wire, it cannot either slip out or move about in the duct; but wire being chosen which does not fill it up, the flow of the juice is not hindered. Three threads having then been passed through the wall of the duodenum near the duct, the intestine and omentum are replaced in the abdomen, and the duodenum fastened by the threads to the abdominal wall. The wound is then sewed up, care being taken that the twisted part of the lead wire passes through the wound. Twenty-four hours after the operation the stitches are taken out, but the wire left in. In two or three days afterwards the juice can be collected. For this purpose the animal must be supported by two straps which pass under its belly, and are attached to a horizontal bar hung from the roof by a cord and pulley. The dog is thus suspended over a table, at such a height that it can barely touch it with its toes, in which position it remains perfectly still.

[The second volume of this work consists of elaborately drawn plates and keys designed to assist "beginners" in manipulation.]

[The following advertisement has been published by Longman and Co.]:

Mr. Cooke's classes of anatomy and physiology serve to illustrate the tablets. They are rapidly conducted, yet the instruction given is complete and exhaustive. The whole of anatomy (on the dissected body), and of physiology (with microscopical preparations and vivisections) are gone through carefully every three months; and the principal points are again glanced at during the fortnight which precedes each examination.

The object of the classes is to enable students to add, to sound practical knowledge previously and slowly acquired, that readiness and precision in details, which are daily becoming more requisite at examinations. The classes are not intended to help idle students to make up, by any artificial method, for time previously mis-spent.

[Address.] T. Cooke, Esq., M.D., 30, Gower Street Bedford Square.

Dr. Powell had, however, so far as he could remember, in his experiments on a dog obtained results similar to those of Dr. G. Johnson and others. He wished, however, to draw attention to the fact that the same phenomena were not observed in experiments upon different animals. In a series of experiments which he had commenced last summer, he had found that in the cat, instead of closure, powerful abduction of the cords was obtained on galvanising the recurrents; and he thought it very important that we should ascertain which animal man resembled as regards the innervation of the larynx, in order to understand better the mechanism of nervous dyspnœa in aneurism. If man resembled the dog or the rabbit in this respect he might have spasm of the glottis as the result of irritation of the recurrent nerve; but if he resembled the cat, the so-called spasmodic dyspnœa, when of purely nervous production, was really due to paralysis. And it was even possible that a ready means of relief might be found in galvanism, for nothing could be more striking than the instant relief afforded to the dyspnœa in the cat when the divided recurrents were galvanised.

. . . .

Dr. Johnson, in reply, said there must be some fallacy in Dr. Reid's experiment quoted by Dr. Powell; it did not agree with Dr. Powell's results on the cat, which were in accord with those of Dr. Rutherford.—*Dr. G. Johnson, British Medical Journal,* No. 729, p. 791–2.

Dr. Day, Lancet, No. 2,682, p. 120. [*See also* p. 15.]

Experiments which have been made on the physiological action of codeia tend to show various results. These in some measure are due to the experiments having been conducted on animals of different species, genera, and classes. Some, and those most reliable, have been on man; and, as it is for human benefit that we prosecute these researches, it would be better if further secondary experiments were always so conducted.

. . . .

Dr. Stocker injected some cats subcutaneously with hydrochlorate of codeia. In each instance the pupils were dilated; cerebral congestion was present, as determined by ophthalmoscopic examination; there was much reflex excitability; in one case, epileptic convulsions; salivation and purging occurred in two cases; there was no vomiting. The dose used was about a grain and a half.

In the case quoted there are several points of disagreement with these results, which are probably due to the difference in the animals—one a man, the other a cat. Thus the cat's pupils were dilated, the man's contracted, and, while there was no increase of alvine or salivary secretions in the man, two of the cats were salivated and purged.—*Mr. Moore, British Medical Journal,* No. 696, pp. 576 and 577. Professor Owen, ["Vivisection, is it necessary or justifiable?"] page 112.

Dr. Bigelow, Professor of Surgery at Harvard University, being extract from the annual address read before the Massachusetts Medical Society, 1871.

British and Foreign Medico-Chirurgical Review, No. 110, p. 283.

The meeting of Convocation of the University of London has this year been remarkable for two things. The first was the passing of a resolution recommending the admission of women to degrees. The second was the refusal to entertain a resolution requesting the Senate not to allow painful experiments on living animals to be carried on at the Brown Institution.

This latter resolution was a direct blow aimed at vivisection, and was moved in a most able speech by Mr. Hutton, M.A., a gentleman of great influence. Only sixteen voted with him and fifty-nine against,—a result, we believe, partly due to the Chairman reading a remarkable letter from Dr. B. Sanderson, the learned Superintendent of the Brown Institution, who stated to our amazement that the laboratory was not used for physiological inquiries, only for investigations into the nature and treatment of disease. It was necessary, he added, to perform small experiments, such as the abstraction of a little blood, &c. We have expressed surprise at this statement. Can it be possible that Dr. Sanderson is ignorant of the fact that physiological teaching is carried on at the Brown Institution, and that such teaching is based on physiological experiments of the most painful kind? The controversy on vivisection has been best handled in the columns of the "Spectator," and most men have come to the conclusion that for proper purposes, within certain limits, vivisection is justifiable, but that anæsthetics should be employed whenever possible. Indeed, it has been urged by many that pain is very seldom inflicted, because the use of anæsthetics is universal. Now, this we deny. In several places in London most painful experiments have been recently performed without producing anæsthesia, and the Brown Institution is one of them. Indeed, after Dr. Sanderson's letter, we think it right to assert that, whether he knows it or not, the use of anæsthetics is the exception, not the rule, in the institution.

We take the liberty, too, of describing two of the experiments lately done, and we suppose frequently done, for teaching purposes, in order that Mr. Hutton may at least have a faint idea of the facts he might easily collect.

First experiment.—Take a lively frog and tie his four legs to a square board, stretching the legs so that he cannot writhe; crucify him, in fact. Then make two cuts, one on each side of the sternum. Another cut across the breast bone is the next step. Then cut through the bone, and take it right out.

The next step in the vivisection is to make a cut the whole length of the abdomen, so as to open the cavity. The end of the heart, which is now visible beating, is to be cut off. Through the opening thus made in the heart push a cannula right up to the bulbos aortæ. Now open the abdominal vein. All this in preparation for the experiment itself, which is thus proceeded with: Inject warm distilled water into the cannula until the whole of the blood has been washed out of the frog, when he will appear to be dead, and swollen up to about four times his original bulk. The injection takes some ten minutes. After the water an injection of silver nitrate is to be made.

Second experiment.—Press your finger under a frog's mouth until the eyeball protrudes. Then pull down his nictitating membrane with a pair of forceps. Next, scrape off with a sharp knife the three layers of anterior epithelium. Now let him rest ten minutes. You may then observe his actions; he pokes his head down between his fore legs, jumps, or turns over, wriggles, and otherwise acts in a strange manner.

Having watched this, take him again and push out the eyeball once more. Again hold down the protecting membrane, and rub a stick of solid lunar caustic all over the eye until the aqueous humour of the anterior chamber shows a precipitate. Now release your frog, and his actions will be similar to those previously watched, but more intense; in fact, he plays such fantastic tricks as few could look upon without that blunting of sensibility on which so many have dilated. It is necessary for him to be left for ten minutes, after which his head is cut off with a pair of scissors, and so his suffering ended.

The object is, to demonstrate the structure of the cornea by staining the intercellular substance. We do not propose to assert that these experiments are useless, but we do say that they could be just as easily performed under the influence of anæsthetics. If Mr. Hutton has any doubt that they are done, we have none. We beg to say that they have been done since his speech in Convocation, since Dr. Sanderson's letter, and done, too, without chloroform or any other anæsthetic.

We have no desire to put an end to scientific investigation, but needless cruelty seems to require curbing, and Mr. Hutton is fighting in a good cause. If he wants details of other experiments, he has only to read the "Handbook" edited by Dr. Sanderson himself, and be informed that that work is used as a text book at the Brown Institution. So it is in most of our medical schools. In the majority of the latter chloroform is used.—*The Doctor*, June 1st, 1874, p. 101.

In reference to the above, Dr. B. Sanderson wrote to *The Doctor*, July 1st, 1874, as follows:—

"Sir,

"My attention has to-day been drawn to an article "in your journal of June 1st, headed 'Vivisection,' in "which you comment on the management of the laboratory "of the Brown Institution. All that is necessary for me "to say with reference to the article is, first, that so far as "relates to the laboratory of the Brown Institution, the "assertions contained in it are untrue; and secondly, that "the statements with reference to this subject which were "embodied in the letter to the Chairman of Convocation "of the University of London, to which you refer, are "perfectly correct.

"Your obedient Servant,"

"The Brown Institution, J. Burton Sanderson.

"June 26th, 1874."

[We are amazed at this letter, which we invite the writer to reconcile with the facts. The assertions contained in our article are true. We did not comment on the management of the "laboratory." Does Dr. Sanderson mean to deny that the experiments we described in *The Doctor* for June 1st have been performed in the Brown Institution? We deliberately repeat that within the walls of the Institution such experiments have been frequently performed.—*Ed. Doctor.*]

X. Dec. 8th.—Letter to *Nature*, No. 216, p. 121.

Nature, August 13th, 1875.

The Gazetta Italiana di Milano contains an essay of Professor Mantegazza on experiments carried on under his direction at the laboratory of experimental pathology of the University of Pavia. It will suffice to state that the experiments were intended to study the action of pain on digestion and nutrition. They were, as the Professor himself confesses, agonizing to the animals subjected to them and distressing to the experimenters, and simply proved that loss of appetite, great weakness, and a peculiar imbibition of moisture were the result of the pain inflicted. It is added that no alteration of the spinal marrow could be detected after the agony had been protracted for one month very meagre results of unpardonable cruelty.—*Lancet*, No. 2,482, p. 415.

DIGEST OF THE EVIDENCE.

Sir THOMAS WATSON, Bart., M.D.

Physician in Ordinary to the Queen, formerly President of the Royal College of Physicians, and member of the Medical Council, 1.

Has been 50 years in the medical profession, 31. Has published a work on vivisection, and has bestowed much thought on the subjection of live animals to scientific experiments generally, 2–6.

equency experi-nts.

Cannot say whether experiments on living animals have grown more frequent of late or not, 104–5. Believes they are more common abroad than in England, 117. Has never witnessed any such experiments himself, 32–3, 62; but has made himself acquainted with the results of Majendie's and of other similar experiments, 64–5.

Considers the infliction of animal pain is a great evil, only justifiable when there is a direct prospect of greater good, or of solving a doubt, 91–3.

tigation human ffering.

Believes, however, that knowledge is obtainable at a small expense of animal suffering whereby human pain may be mitigated and even life itself preserved, 8; and is of opinion that the present state of surgical knowledge could not have been reached without such experiments, 34.

scovery of e circula-on of the ood.

Results obtained by Experiments.—Although the discovery of the circulation of the blood was verified, rather than made by vivisection, 84; it was aided and perfected by Harvey's innumerable vivisections, 35; and microscopic investigations into the hearts of animals, 85–8. From this discovery the cure of aneurism followed, and Harvey was enabled to get rid of a dangerous tumour by tying the artery feeding it, 35.

the treat-ent of eurism.

the func-ons of the rves.

The experiments of Sir Charles Bell and Dr. Marshall Hall on the nervous system enabled drugs to be applied in new ways for the soothing of pain and the diminution of danger to life, 35.

Induction of Disease.—Believes experiments as to the induction of disease are designed to ascertain the exact cause of the disease with a view to its prevention, 98; has no personal knowledge of the subject, 99; but thinks them of but little use, 61. Is not aware of any experiments having been made with regard to the induction of disease on grouse or other animals, 96–7.

Pharmacological Experiments.—New drugs and remedies are tried on animals, but the effect on animals often differs widely from that on man, and experiments may be therefore at once painful and misleading, *35f, g*, 58; a drug which will poison a dog may not be poisonous to a man, 57. Experiments are, however, sometimes made on animals with the view of ascertaining the action of poisons, and of bringing the results to bear in legal investigations, *35e*.

edical rispru-ence.

itigation animal ffering.

The knowledge of the effect of a drug on a single individual animal may save many animals from pain, 59; and such experiments are justifiable therefore, 60; as also giving animals special diseases, 61.

Limits of Experiment.—Considers experiments on live animals are necessary, 41; and justifiable, but only when undertaken with a definite object, and performed by a skilful anatomist with proper apparatus and after due study and preparation, 9–10, 13–16, 18, 71. Experiments made simply to see what will happen are inexcusable, 12.

xperi-ents by competent ersons.

Has no knowledge as to the extent to which experiments are performed by incompetent persons, *35h*; but thinks they must generally be useless and should therefore be put down, 37–8; there are very few persons in the country who are competent, or who should be allowed, to conduct such experiments, 106.

or teaching urposes.

Experiments for the sake of demonstrating accepted facts to classes should be forbidden, 39–40; after once the result is established experiments should not be repeated, 17; such repetition is cruel and useless, 67–70; complicated experiments often prove nothing and should not be allowed, *35i*–36.

n the iving issues.

Does not approve of such experiments as those for the purpose of studying the living cellular tissues unless a definite object which would alleviate human suffering is in view, 89–90.

or surgical ractice.

Doubts whether the practice of surgical operations on a live animal would be of any use to the student and thinks they should not be allowed, 72–3.

Watson, Sir Thomas.

Sensibility of animals.

Does not know whether the sensitiveness of the different orders of animals to pain varies, and cannot tell how it could be ascertained; some, however, think the highest orders feel most acutely, 100–3.

Harvey's experiments.

Anæsthetics.—A new era in experimentation commenced with the introduction of anæsthetics, 35; when Harvey examined the double hearts of vertebrate animals and the single ones of molluscs and insects, *35a, b*, anæsthetics were not known, many of his experiments would now be performed painlessly, *35b, c*.

Nearly all experiments may be made entirely or comparatively painless by the use of anæsthetics, 42–3; even if the manifestation of pain is essential to the success of the experiment the amount of suffering can be lessened, 19–24.

Cannot always be used.

The use of anæsthetics would frustrate the objects of many experiments on the nerves and possibly of some experiments as to the action of poisons; anæsthetics themselves being to a certain extent of the nature of poisons, 53–6; but witness is not aware of any other cases in which they would interfere with the result, 54.

Experiments on th nerves.

In Sir Charles Bell's experiments the nerves of motion were distinguished from the nerves of sensation by the presence or absence of pain, and the use of anæsthetics, had they been known, would have defeated the object of the experiment, 47–50; lingering pain, however, was not necessary, 51–2; considers that it is never necessary, 25–6, or justifiable, 44; by lingering pain means pain felt after the influence of the anæsthetic has departed, 94–5.

Effects on lower animals.

Has no knowledge of the effects of anæsthetics on the lower animals, 74.

Chloroform.

Considers that the use of anæsthetics should be compulsory, 29–30; chloroform is the anæsthetic best understood, 63.

Curari.—The effect of the curari or worari poison is to deprive an animal of motion, and it therefore might be used to facilitate an experiment, but to deceive lookers on by saying it destroyed sensation also would be a fraudulent trick, 75–83.

Licenses to perform experiments.

Regulation of Vivisection.—Thinks that licences should be granted by the Home Secretary or some other high authority, on the professional recommendation of the Inspector of Anatomical Schools or some similar adviser, 107–111, 113–4; licences should be general, not for particular experiments only, 118; and should be subject to revocation if abused, 119.

Thinks that it would be an invidious task for either the College of Physicians or College of Surgeons to undertake the granting of such licences, 115; but observes that his views with regard to the licensing system have been in his mind only since talking the matter over that morning with Sir George Burrows, 121.

Cruelty to Animals Act.

Has not considered whether it would suffice to strengthen the present Cruelty to Animals Act and throw on the experimenter the *onus* of proving that he himself was a fit person, and the object of the experiment a proper one, 120.

Inspection of physiological laboratories.

Would prefer to have an inspector of physiological laboratories like the inspectors of dissecting rooms and schools of anatomy, and would leave the rest to the conscience and humanity of the experimenter rather than attempt to place restraints by law, 116.

Both branches of the medical profession are entirely desirous of mitigating pain, and would concur in any legislation having that result, 27–8, 45–6.

Sir GEORGE BURROWS, Bart., M.D.

President of the Royal College of Physicians, late President of the Royal Medical and Chirurgical Society, &c., of the General Medical Council of the United Kingdom, 122–4; and for 30 years was the physician and principal medical teacher at St. Bartholomew's Hospital, 180.

Nature of experiments made by witness.

Has witnessed and has performed some operations on live animals, 125; the object of the latter was to elucidate the condition of the blood vessels of the brain under different modes of dying, 126. Death in all cases ensued in less than five minutes, 127–8, 130; sensation would cease before death, 130; and the pain produced would be less than from the ordinary methods of killing, 131.

Of those seen by witness.

The experiments seen by witness were performed by Dr. Charles J. B. Williams and by the late Dr. Hope to determine the cause of the sounds of the heart in health and in disease, and they resulted in the introduction of improved method of treatment of heart disease, 132–3. The animals were rendered insensible before being operated upon by curari, 132.

Physiological Handbook.

Frequency of Vivisection.—Has no personal knowledge as to how much vivisection is practised out of London, 181; but knows that the number of experiments made at St. Bartholomew's in 30 years was very small. Dr. Legg's experiments on the biliary fistula of cats were made subsequent to witness leaving Bartholomew's Hospital, 227. Cannot give much information as to Majendie's visit to this country, 257–8. Does not believe that medical students practise much vivisection, 204. Is aware of the existence of a "Handbook for the Physiological Laboratory," which would seem to imply that these experiments are more frequent than witness is aware of, but it has only recently appeared, and is, in witness' opinion, for teachers rather than students, 205–7.

Antiquity of vivisection in England.

Vivisection is no new thing in England; in addition to Harvey's private experiments he demonstrated the circulation of the blood by experiment on the living animal to Charles I., his queen, and the princesses, and the animals in the royal parks were placed at his disposal for his investigations, 138.

Development of practical physiology.

The experimental method is thought more highly of than formerly, and is growing in physiological laboratories, although not in medical schools, such as St. Bartholomew's, 230–1; and physiology is now practically taught in a way in which it was not taught before, 232.

Improved treatment.

Results obtained by Experiment.—These experiments increase knowledge, and increased knowledge leads to the alleviation of human suffering, 233; has himself seen improved methods of treatment result therefrom. Considers such experiments are necessary for the progress of medical science, 134; thinks Sir Charles Bell's expressions of reluctance to perform certain experiments, on the ground of the pain they must inflict, probably refer to some performed by Majendie about the same time, 221–2.

Sir C. Bell's nerve experiments; benefits derived therefrom.

Sir Charles Bell's experiments on the facial nerve would not cause more pain than the prick of a spur, 141–3; but yet they resulted in enabling a facial paralysis proceeding from a temporary cause to be distinguished from a serious one proceeding from a diseased brain, 142; previous to this discovery the facial nerve was often divided by surgeons to cure tic doloreux; the knowledge that it was not a nerve of sensation showed this to be useless, 215.

Dr. Marshall Hall.

The reflex action of the spinal cord was discovered by Dr. Marshall Hall's experiments in which the spinal cord was severed, and the functions of the part below the section ascertained, and symptoms which formerly were referred to disease of the brain were found to proceed from the state of the spinal cord; gives instance, 184–7.

Claude Bernard.

The vivisections performed by Claude Bernard established the fact that, in addition to the secretion of bile, the liver elaborated the materials which form the saccharine principle of the blood, 188; a result which could probably have been arrived at in no other way, 189–90. Such experiments could not in the main have been performed on the human subject without resulting in death, 191. Harvey's discovery of the circulation of the blood was merely an addition to scientific knowledge at the time, the important advantages resulting from the discovery were not foreseen, 244–8.

Sounds of the heart.

Admits that it may have been within the limits of possibility that the discoveries as to the sounds produced by the heart might have been arrived at by the comparison of a large number of carefully tabulated cases; but points out that as a fact no such result was obtained by that method, 214.

Necessity of experiments.

Limits of Vivisection.—The cases in which vivisection is necessary are very rare, 174; it is, however, sometimes necessary both for the progress of knowledge and for medico-legal investigation, 153–4.

Experiments for teaching purposes.

Experiments for the sake of illustrating known truths in the schools should not be allowed, 139, 175, 199; nor should experiments made from pure curiosity, 239–40.

Is of opinion that if there is a reasonable prospect of an experiment advancing knowledge, settling a discordance of opinions, for instance, it should be performed irrespective of any ulterior benefit being directly attached to it, but should be done with proper precautions, 235–9, 242.

Competent men only should be allowed to experiment.

Would separate experiments of this kind from all others; students should be deterred from performing them, although it is conceivable that a young man with a thorough knowledge of the science might advance knowledge, 211, 700–3; as a rule, thinks that persons who have not a thorough knowledge of anatomy and physiology ought not to be allowed to undertake these experiments, although by chance a useful result might be arrived at, 149–51, 198.

Induction of disease.

Considers the induction of disease, tubercle for instance, for the purpose of elucidating the causes and conditions of the disease quite justifiable, although attended with suffering, 216–8.

Action of drugs.

Approves of ascertaining effects of drugs and poisons by experiment on animals, and thinks that such experiments have been most useful, 219–20; although the knowledge obtained is necessarily imperfect; 259–61.

Anæsthetics.—The majority of experiments could be, and ought to be rendered painless, 160, 249–50. The experiments performed by Harvey in his researches, touching the circulation of the blood, for instance, might now all be rendered painless, 38.

Experiments on the nerves necessarily painful.

Some experiments, however, cannot be performed under the influence of anæsthetics, 162; some on the nervous system are necessarily more or less painful, all others can be performed without causing pain, and in those which cannot, such as dividing the spinal cord, the more painful part, the actual cutting, can be done while the animal is under anæsthetics, 144, 192–5, 251; many experiments on the nerves are, however, not of a serious nature, 140; is not a scientific physiologist, but doubts whether any means exists of rendering all experiments on the nervous system painless, 196–7.

Physiological Handbook.

The experiment referred to in the "Physiological Handbook," and entitled "excitation and section of the spinal cord in the rabbit," would be both lingering and painful, cannot say whether anæsthetics would interfere with its object, 208–10.

Painful experiments on frogs.

Does not know whether placing frogs under the influence of curari, slitting them open, dragging out the mesentery and placing it under the microscope for two hours, would be justifiable or not without seeing the experiment and knowing all the conditions, 243; the amount of pain justifiable must depend on the importance of the object sought, 145.

Can give no information as to the effect of anæsthetics on frogs, 228–9.

Curari appears to render animals insensible, but is not an anæsthetic because it destroys life, 135–7; if it can be shown not to destroy sensibility it should not be used, 212–3.

Licences.

Regulation of Vivisection.—Suggests the licensing of particular places for such experiments, 173; and thinks that the few operations that cannot be performed without pain should only be allowed under sanction of some authority guided by a responsible person possessing a thorough knowledge of anatomy and physiology, 163, 252–4.

Adviser to the licensing officer.

Qualification and functions of adviser.

Considers it essential that the controlling authority should act under professional advice, which would command the respect of the profession, 164–6; and that he should have functions analogous to those of the Inspector of Anatomy, 167; and should have a knowledge of the character, position, and attainments of the individual, 255–6; and be himself a good anatomist and physiologist, and retain office *quam diu se bene gesserit*, 172.

Anatomy Act.

Instances the former scandalous manner in which the practice of anatomy was sometimes conducted, and the good effects of the Anatomy Act, and of the appointment of inspectors of anatomy, 167–71.

Is of opinion that to require permission to be obtained for every experiment on live animals would be an overgreat interference, but thinks a series of such experiments should be undertaken only under some controlling authority, 152.

Necessity of despatch in obtaining permission.

Persons skilled in anatomy and physiology should not be refused leave to conduct such experiments elsewhere, 176–7; cases might easily arise in which the surgeon or physician might wish to fortify his opinion as to the course to be adopted, by first trying it on an animal, in such instances the delay occasioned by having to get leave would be serious, 178–9.

Miscellaneous.—Considers the members of the medical profession as humane as other men; they would readily

Burrows, Sir George.

assent to any reasonable proposition for checking abuses, 146–8.

lar
ies on
ubject.

Believes that popular opinion has been excited partly by the discovery of certain cases of abuse, and partly by ignorance of the real nature of vivisection, 159; and a prevalent belief that it is a dissection of the living animal; it ought to be made known that very often the operations are of a most trifling character, such as in inoculation, and often there is no operation, but the administration of a drug only, 155. On the other hand there have been great abuses in operations on the living animal which should be put a stop to, 156–8.

tence of
es.

SIR JAMES PAGET, BART.

President of the Royal College of Surgeons and of the Medical and Chirurgical Society, 262, &c. &c.

ease of
riments
nimals.

Has given much attention to experiments on animals, 263; considers that physiological experiments have much increased in number since Sir Charles Bell's time, but thinks when he speaks of their being then monstrously prevalent, he refers to the French School and Majendie, whose experiments, although they have led to the saving of lives, were needlessly repeated to classes, 349.

Believes such experiments are not performed in England at all, except in some schools of medicine and by some physiologists connected with them, 307.

siolo-
l Hand-
k.

Considers Dr. Burdon-Sanderson's handbook clearly designed to aid advanced researches and not for ordinary students, 354–6.

Results obtained by Vivisection.—Such experiments are often necessary in novel cases of injury, 271–5. Gives instances of the advantages resulting from experiments on animals. The knowledge of the method of curing aneurism by tying the artery, and the means essential to recovery were learnt from the animal vivisections of Hunter and those who followed him, patients' lives were formerly lost from ignorance on those points, 294–5; admits that the method, however, might have been learnt from observations on men only in time, but points out that it was more quickly learnt and completed by experiments on animals, 294.

e of
urism.

nt of an
idote for
ke
son.

Further illustrates the necessity for experiments on animals by referring to the desirability of speedily finding an antidote for snake poison; such a remedy can probably be discovered only by trying various drugs, &c. on men and animals bitten; if only on those accidentally bitten the number of cases in which they can be tried must be very small, and the chance of discovery remote, but by trying experiments on animals inoculated with the poison the number of cases may be indefinitely increased and the discovery of an antidote probably proportionately accelerated; in the meanwhile 20,000 people a year, it is said, die from this cause in India alone, 305.

eatment
' angina
toris."

Dr. Brunton having observed that in *angina pectoris* extreme tension of the blood vessels accompanied the paroxysms, exposed the blood vessels of living animals, and after trying various substances found that nitrite of amyl possessed the power of relieving the tension of the vessels, and this substance is found to check the agony and probably avert the sometimes fatal result. Dr. Brunton's experiments might be performed nearly if not entirely under chloroform, and could not have been attempted on the human body, 308–15.

ansfusion
blood.

As another instance of the advantage of experiments on animals, refers to the discovery of the possibility of the transfusion of blood, of the causes of its frequent failure, and of the manner in which they may be averted. Had it not been possible to experiment on animals it would have been abandoned as impracticable before being brought to its present state of perfection, 380.

sk attend-
g the use
chloro-
m.

Also refers to the negative evidence obtained, that no certain means of averting the occasional fatal effects of chloroform exists; has himself seen four deaths therefrom, and has reverted to ether, in spite of its inconvenience, in consequence; by experiments on animals an anæsthetic both convenient and safe is being sought for, 380.

Anæsthetics.—A very large number of experiments can now be performed under chloroform, 278; Hunter's experiments would now be conducted under chloroform and the animal only subjected to the trivial pain of recovery, 296; some painful experiments, however, are necessary in the promotion of science, 293, but their number is very small, 297; Majendie's scientific researches might have been as successfully prosecuted with less animal suffering; he appears to have been quite indifferent to animal pain, 368–74.

ajendie's
xperi-
ents.

Paget, Sir James.

All such experiments should be performed so as to minimise the amount of pain, 298–301; death under anæsthetics is painless, 381.

Believes the lower animals have greatly diminished sensibility, experiments can generally be performed after the brain has been removed, as in frogs for instance, 357.

Sensibility of animals to pain.

Believes the pain caused in studying inflamed tissues in the frog to be small, 358–60; and not very great in bats, 361–2.

Study of Physiology.—Physiology is now a branch of study, and physiological laboratories are attached to hospitals, 316; the students are required to attend a course of practical physiology, but are not required to perform experiments on living animals, and, as far as witness is aware, they do not perform them, 285–9.

No special arrangements are made at St. Bartholomew's and the larger hospitals for living animals, the bulk of the work consists in the microscopic examination of tissues, &c., and the chemical testing of the animal fluids, &c.; the provision for live animals at Edinburgh is exceptional, 317–9; the elaborate machinery for the administration of anæsthetics tends to the reduction of the amount of pain.

Physiological experiments at hospitals.

Laboratory at Edinburgh.

Thinks the physiological school may be unduly developed.

Thinks that experiments for ascertaining the effects of poisons and drugs are increasing, but those for physiological and surgical purposes diminishing materially, most facts connected with the latter having been ascertained, 345–7; the effects of poisons and drugs and the progress of diseases cannot be studied under chloroform, 278.

Increase of experiments.

Limits of Experiments.—Considers experiments on animals should not be appealed to until all other methods of settling a moot point have been tried; is inclined to think it is now frequently resorted to prematurely, 302; experiments should be strictly limited to those from which there may be a reasonable expectation of discovering new facts, 363; the cases in which it is necessary to have an animal under experiment are very rare, 344.

Painful experiments should not be allowed in teaching, 282–4, 290; and even under anæsthetics should be limited to the illustration of facts which cannot readily be apprehended from description and diagrams only, 291; such as the action of the heart as seen in a decapitated turtle, or, in a warm blooded animal under anæsthetics and kept alive by artificial respiration, 292; this experiment can be shown in 20 minutes or half an hour, the animal remaining wholly under anæsthetic influence, 375–8; but speaking generally, classes can be as well taught without experiments as with them, 375.

Experiments for teaching purposes.

Demonstration of the action of the heart.

The live animals said to be used for purposes of demonstration at Guy's Hospital are probably insensible; believes live animals are never so used at St. Bartholomew's, 352–3. Dead animals are of very little use in the study of anatomy, 342–3; knows nothing of the experiments at Florence, Leipzig, Vienna, or Paris, 379; foreign methods are not common in English schools, 351.

Demonstrations at Guy's Hospital.

Regulation of Vivisection.—Approves of the resolutions passed at the meeting of the British Association in 1871, to the effect that the use of anæsthetics when possible should be compulsory; that no painful experiments should be made for teaching purposes; that no unskilled person should be permitted to perform such; and that they should not be practised in learning veterinary surgery, 267; believes that these resolutions are supported by all the leading scientific men of the day, 268–9, who would cordially support any reasonable law based on them, 270. The leading men in physiology and medicine are as desirous as other men for the promotion of humanity and abolition of abuses, 279–81. Medical men may feel somewhat doubtful as to whether they would not prefer that the control should be exercised by public opinion rather than by law, 281. Believes that public opinion would prevent the abuse of vivisection, 341; and be a sufficient restraint without legislation, 329–330; if a law is to be made, thinks it should provide for licensing teachers of physiology in the same manner that all teachers of anatomy are now licensed by the Secretary of State, 328–32; no private practitioner is allowed to, nor does, dissect, 333–5.

The British Association resolutions.

Public opinion on error.

The Home Secretary should be aided by advisers as to the competency of the person applying for a licence in the same manner as in the case of teachers of anatomy, in which the signature of two magistrates is necessary, 336. Is of opinion that unfit persons should be prevented from experimenting, and that only persons of

Licences.

Nature of experiment to be left to experimenter.

high scientific attainments should be allowed to perform them, and that the propriety of performing any experiment should be left to the humanity and judgment of the experimenter, 364–6.

Demonstrations.

At present the arrangements as to experiments are entirely in the hands of the lecturer on physiology, 320, 325; thinks this wrong; no experiments on living animals should be made except under sanction of a committee of the officers and lecturers or even governors of the hospital, 320–1, 326. When there is no medical school the performance of such experiments might safely be left to the discretion of a body of surgeons, 322–4.

Objections to legislative restriction.

Admits that it might, however, seem unreasonable to compel men thoroughly conversant with such experiments to apply for permission, 327; points out also that a private practitioner might sometimes find it highly desirable to try a special operation on an animal before performing it on a human being; a law of the nature suggested would make this illegal; thinks therefore a law would be inexpedient, 337–40.

Fear of fettering scientific research.

Considers that many things essential for the preservation of human life can only be ascertained by experiments on animals, and that medical men seeing much human suffering and death resulting from things they cannot yet cure, naturally attempt to discover remedies for them, even at the expense of animal suffering, and therefore is anxious lest in putting down abuses, undue restraint should be put on scientific research, 382–5.

WILLIAM SHARPEY, M.D., LL.D., F.R.S.

Professor of Physiology for more than 30 years at University College, and for nearly 20 Secretary to the Royal Society, 386–7.

For the increase of knowledge,

Necessity of Experiments on Live Animals.—Has performed experiments on living animals, and sometimes exhibited them, 389–91, and considers such experiments absolutely necessary for the progress of physiology, 393; and that scientific investigation by competent persons is important for the development of medical and surgical improvement, 398–401; reads extract from Haller in support of this view, 592–3. Is of opinion that the knowledge derived by really scientific observers from experiments on animals is most useful in interpreting the results of observations on the human subject in disease, 406–7; and that in order to deal rightly with diseased conditions of body, its condition in health, and the causes of its change of condition must at any rate be highly desirable.

and ascertaining the action of drugs.

Thinks, too, that students should see the effects of poisons, so that they may at once recognise them in man; points out that one animal would suffice for 300 students; and that although chloroform could not be administered death would be speedy, 507–11. Considers that the effects of new drugs should be first tried on animals, 504–6.

Stethoscope.

Results obtained by Experiment.—Sometimes there is a direct connection between increased knowledge and improved treatment, for instance, the use of the stethoscope became possible only when the connection between external sounds and internal conditions had been established; the discoveries of Harvey and Sir Charles Bell have been followed by important medical improvements which could not have been foreseen at the time, 395–7. The feasibility of tying large arteries, the best kinds of ligature, the influence of the periosteum in removing dead bone and reproducing bone have all been ascertained by experiment. Would, however, lay stress on the additional knowledge acquired rather than the improvement in the art of healing resulting from vivisection, 394.

Functions of the periosteum.

Galen's discoveries.

Instances, as illustrations of the advancement of science by means of vivisection, the discovery of Galen, that the arteries contained blood, and not vital air, as was formerly believed; admits that Harvey was led to reject the opinion in his day commonly received from the arrangement of the valves in the arteries, but the fact of the circulation of the blood and the true nature of the motions of the heart were only fully established by vivisection. The existence of the capillary vessels by which the blood passes from the arteries into the veins was established by the microscopic researches of Malpighi on the transparent parts of cold-blooded animals. The pressure of the blood was measured by Stephen Hales, Poiscuille, and Ludwig, and its rate of circulation ascertained by experiments on live animals, 394.

Functions the capillaries.

Sensory and motor nerves.

The sensory and motor functions belonging respectively to the posterior and anterior roots of the spinal nerves were discovered by the vivisections of Sir Charles Bell, and fully demonstrated by those of Majendie, 394. The functions of the spinal cord, medulla oblongata, and other nervous centres, and of particular portions of the brain, as far as they are known, have been ascertained by vivisection, 394. The nature of the reflex action of the nerves has been similarly arrived at, 394; as also the discovery of the functions of the facial nerves by Sir Charles Bell and Herbert Mayo, which at once changed the old treatment for tic doloreux, 394. The connection of the pneumo-gastric nerve and the medulla oblongata with the movements of respiration of the heart and vocal organs were discovered by vivisection, 394. The discovery of the vaso-motorial system of nerves, on its dependence on the medulla oblongata, and of the true explanation of the phenomena of blushing all resulted from vivisection, 394.

Nerve centres.

Reflex action.

Vaso-motorial system.

The immediate causes of the arrest of the functions of the brains and the motion of the heart in asphyxia and the correlative knowledge of the methods of resuscitation have been ascertained by vivisection, 394, also the conveyance of gases to the tissues by the red portion of the blood, and the effect of certain gases on the blood, 394. Vivisection brings increased knowledge, increased knowledge brings improved remedies and improved treatment, 394.

Red corpuscles of the blood.

Sensibility of Animals.—No animal, not even the lowest, has been proved to be free from pain under such experiments, 516; but it is difficult to say whether movements of animals experimented on indicate pain or not, 516.

Relative sensibility of different classes.

Can hardly say whether vertebrated suffer more than invertebrated animals; the writhing of a worm on a hook may be from muscular excitement and independent of pain, 512–4. A polyp may be cut into pieces and each grows into a new animal; thinks, therefore, the pain can hardly be severe, 513. Invertebrated animals, except insects, show small sensibility; in vertebrate animals it appears to be more acute, but it differs, or rather the manifestations of pain differ, 502, in individuals of the same species as pointed out by Dr. Waller and Vesalius, 496–7.

In different individuals.

Painful Experiments.—Does not approve of lingering and painful experiments generally; if it is not clear that the results will be useful and decisive they should not be performed, 446–7, 578–9; but even a lingering and painful experiment is justifiable if it be for a great scientific end, and if it will probably lead to a decisive result, 576, and is performed by a very competent person, 416–9, 425, 428. The number of experiments entailing severe pain is very small, 415. Pain should be minimised, 452; and if recovery after an experiment would be attended with pain, the animal should be destroyed, 451.

Pressure of the blood. Effects of starvation.

Thinks experiments as to the pressure of the blood must be very painful without anæsthetics. Starving animals to death would be another instance of protracted suffering, 470. Would not have undertaken such an experiment; it might be worth doing once but should not be repeated, 572–4. Refers to a long and tedious experiment for ascertaining the effect of mercury on the flow of bile which was made by Dr. Bennett at Edinburgh, 575.

Investigation as to the uses of the bile.

Reflex action.

The brain must remain in action in experiments with regard to the controlling centres of reflex action, 533; but the destruction of the upper part of the spinal cord destroys sensation in all parts below the medulla oblongata, while organic life may be maintained, in the case of cold blood animals for days even; this was Sir Benjamin Brodie's method, 490–5.

Inflammation of the cornea.

The experiment of causing inflammation in the cornea of a frog's eye may not be very painful, and it might be performed after the brain had been destroyed, 548–51.

Biliary fistula in cats.

Thinks it quite possible that Dr. Legg's experiments on 16 cats, some lasting three or four weeks, put to a lingering death, with a view of testing the functions of the liver, may not have been advisable, 577.

Schwann's experiments.

Some severe experiments on the gall bladder were performed by Schwann of Louvain, 575. He connected the gall bladder with an opening in the side of the animal, so as to divert the bile from the intestines, 420–1; with the object of discovering the use of the bile, 426–7; the operation itself would be performed under chloroform, 423; but the experiment would last some weeks, 420–1.

Artificial respiration.

Ludwig has a gas engine for keeping up artificial respiration in the animals; which is also used for driving lathes, &c.; there is a similar one at University College, 552–5.

Experiments on Human Beings.—Has himself made experiments with various medicinal agents on men to see how soon they would appear in the urine; instances also Dr. Stak's experiments on himself, and Dr. Parker's with alcohol, Sir James Simpson's with chloroform, and Spallanzani's on digestion on themselves, 594–6.

ri.

All novel operations are in reality experiments on the human subject; as for instance, Hunter's ligaturing an artery for aneurism, 596. Experiments on men with a view of ascertaining whether curari has anæsthetic properties, are not necessary as safe anæsthetics already exist, 568–70.

an
ection.

Human vivisection is said to have been performed by Herophilus of Alexandria, who was consequently denounced by Tertullian; in modern times inoculation was first tried on criminals, but cannot think the possibility of subjecting criminals to experiments can ever become a practical question, 558–67.

n.

Ancient Vivisection.—Galen describes his tables and appliances, and the manner of vivisecting in the second century; gives details of his experiments on the spinal cord, 499–500.

ius.

Vesalius gives a chapter on vivisection in his great work on anatomy in 1543, gives particulars, 497. He appears to have been in the habit of exhibiting his experiments to a class, 501.

ce,
le
ard.

Modern Vivisection.—Vivisection is far more frequent abroad than in England; in France, Claude Bernard is deservedly eminent, and has been most active and successful in his researches, 517–8.

ndie's
ri-
s.

Majendie's experiments threw light on some matters, but some of them were perfectly unjustifiable, such as cutting out a dog's stomach and illustrating the mechanical action of the contraction of the diaphragm and walls of the abdomen, by inserting a pig's bladder in lieu, 474–5. Attended the first of a series of lectures by Majendie; the experiments were painful (there were no anæsthetics then) and without sufficient object, and the animals were finally killed in a very painful way; witness was so repelled by what he saw that he never went again, 444. Does not think experiments now made in France are so purposeless and cruel as some of Majendie's, but is less conversant than formerly with such matters, 480–1.

ens.

Flourens removed portions of the brains of animals and kept them still alive, and made some discoveries which could not easily have been otherwise made, 476–8; these severe experiments are seldom performed in England, 479.

any.

In Germany scientific men are numerous and zealous and their universities afford scope for all kinds of experiments, 517; of which the advancement of science is the primary object, but they are also employed for the verification of facts; one or two experiments by a single individual can hardly be relied on to establish a new fact, until it has been tested by other observers, 519–22.

d have
te

Limits of Experimentation.—Experiments without a definite object are mere purposeless inflictions of suffering and are of no use, 402–3; although conceivably a discovery might result from one, 523. Would not recommend therefore the practice of experiments by uninstructed persons on the chance of something turning up, 524.

ces-
epe-
.

When facts are once thoroughly established by painful experiment before skilled persons, such experiments should not be repeated, 404–5. In exceptional cases veterinary surgeons might be competent to conduct such experiments, but not ordinarily, 429–30.

aching
ses.

Experiments for teaching should be limited to those which can be performed without pain, 466; such as the action of the heart, which should be shown to students in living animals, 467. Illustrations involving any severe pain should be abstained from in teaching, 539–40; except those showing the action of poisons, 300, 541–2.

l
Dr.
r's and
Bell's
i-
s.

The repetition of the painful experiment, described by Dr. Foster, for illustrating the functions of the anterior and posterior roots of the nerves of the vertebræ, is certainly not necessary for exhibition, and the fact is well established, 536–6.

Thinks that some of Sir Charles Bell's experiments, such as that with regard to the spinal cord, should not be repeated on the ground of their painfulness; and others because the facts are clear and admitted, 464–5.

Anæsthetics.—Anæsthetics have made a great difference in experiments on animals, 534. Most experiments can now be rendered painless, 392, either in whole or in part, 412–3; and should be performed under anæsthetics, 448–51, 590. In tying an artery the operation may take place under anæsthetics, and the pain of the recovery is small, 414. Sir Charles Bell's experiments

on the facial nerve were all but painless, and would have been interfered with by chloroform, 408–9.

Effect of chloroform on frogs.

Thinks it possible that chloroform would destroy life in the frog, 532. Regards the administration of curari to frogs before the experiments described by Dr. Foster as unnecessary, 531. In most cases the brain can be first destroyed, 535. Alcohol acts as a very strong narcotic on frogs, 532. Chloroform, and chloral even more so, interferes with the action of the heart and cannot be used in many experiments. Opium is available however, 556.

Of alcohol.

Chloroform, chloral, opium.

Curari.—Curari is not, like chloroform, ether, &c., proved to be an anæsthetic, it is really given to keep the animals still, 468–73; although by some it is considered to be of the nature of an anæsthetic, 462–3; thinks that it should not be represented to the public as being an anæsthetic, 441–3; Claude Bernard's opinion that sensation remains is of much weight, 440. Considers himself that the curari poison does not destroy consciousness, it cuts off the power of the nerves over the muscles and may destroy sensation, but the last is a moot point and requires further investigation, 435–9; curari has been suggested as a remedy for tetanus, 571.

Extent of the Practice of Vivisection.—Thinks the popular mind is excited by what it hears of vivisection on the continent, 455; has himself heard no evidence as to the existence of any large amount of vivisection, and does not believe that it exists, 456; and has heard no evidence of any excesses in England, 454; on the contrary believes that there are very few painful experiments performed in this country, 584.

Doubts existence abuses in England.

Thinks it probable that young physiologists who have studied abroad, particularly at Leipsic, would be disposed to introduce here the methods in vogue there, but does not believe that experiments are carried on by persons who are not either teachers or investigators, 538.

English students at Leipsig.

Does not think that there are more than a dozen experimenters in this country who practise vivisection, 453; believes it is not resorted to for individual satisfaction, as the results are generally announced in scientific publications, 458–60. As a rule such experiments in England are carried out in the physiological laboratories attached to schools and established under the directions of the College of Surgeons and other examining bodies, 482–4; gives names and particulars, 457; and refers to the judicious experiments made by Professor Syme, 410–1.

Few vivisections in England.

Mostly in physiological laboratories.

Study of Physiology.—Students are required to have a knowledge of practical physiology, but not to perform experiments, 485; and as a rule they do not practise vivisection, 453; recollects, however, an exceptional case, that of Mr. James Blake, who made several valuable additions to scientific knowledge, 488–9. A great portion of practical physiology has nothing to do with vivisection, a great part of the student's work consists in the microscopic examination of the tissues, 486–7. Experiments are sometimes exhibited in the theatre, but more often to a few students only in the laboratory, and are generally performed under the influence of anæsthetics at University College, and probably at other schools, 461.

Agrees with Professor Foster that the methods of experiment are becoming year by year more physical in character, and that observations having the widest bearings on physiology may be conducted for the most part on frogs, 525–8.

Experiments are of a more physical nature than formerly.

Admits that the advance of science opens up new questions as it brings us into wider contact with the unknown, and necessitates new experiments, but thinks the fear that they will increase in "geometrical progression" chimerical, and points out that the advance of science has led to the discovery and use of anæsthetics, and apprehends that all such experiments should be made under the direction of some skilled person, 543–7; does not think that witnessing these experiments tends to blunt humane feelings, 585–6; gives instance to the contrary, 503.

Increase of experiments.

Should be under control.

Regulation of Vivisection.—Admits that the zeal of young scientific men may carry them too far, and that if he had been asked beforehand as to some experiments he should have recommended their not being done, 580; does not, however, believe that an indiscriminate practice of vivisection prevails in this country; thinks that such experiments are very rare except those performed by competent persons, and that therefore no control is needed, 431–4.

The more eminent men in this country reprobate the needless infliction of pain, and have vivisected with the greatest reserve, and have avoided severe experiments

Sharpey, William, M.D., &c.

except when absolutely necessary, and have in fact discouraged vivisection as far as possible, 445.

Deprecates legislation.

Doubts whether abuses requiring legislation exist, believes public opinion and the example of leading physiologists will prevent excesses, 453, 591; if there is legislation it should provide for the licensing of competent persons only, for a record of experiments being kept, and for withdrawal of the licence in cases of abuses, 583, 591; but is of opinion that no restriction should be imposed with regard to animals rendered insensible either by anæsthetics or by destruction of the brain, 451, 453. Points out objections to certain phrases in the draft of a bill on this subject laid before Parliament, 453.

PROFESSOR GEORGE M. HUMPHRY.

Professor of Anatomy at the University of Cambridge, and surgeon to Addenbrooke's Hospital, 596–7.

In medical schools.

Among private investigators.

Extent of Practice of Vivisection.—Does not believe vivisection is carried on to any extent in England, except in the schools of physiology, 638–40, and does not think the number of these reaches a dozen, 763–5; private investigators are very few in number; very little physiological work is done in England, 766–8; thinks that any important discoveries would naturally be speedily announced by those who make them, 774–6.

Increase in number of experiments.

The number of experiments, however, has increased with the number of investigators and the use of anæsthetics, 675, under which such a large number of experiments, especially physiological ones, can now be performed without giving pain, 679, 725–6.

Is not improperly conducted in England.

Experiments by students.

Is unaware of any abuse of such experiments on live animals, believes public statements with regard to them are greatly exaggerated, 619; thinks they are not improperly conducted in England, believes they are in the hands of competent persons, 620; thinks, however, that although a teacher would naturally associate his best students with him in conducting investigations, experiments on live animals should be only under a responsible professor, 627–9, and that it can rarely be necessary for students to practise vivisection, and that when necessary it might almost always be done under anæsthetics, 623–6.

Cambridge laboratory.

At the physiological laboratory at Cambridge the senior students are deputed by the lecturer on physiology to perform experiments on live animals, but only under anæsthesia, 689–4; but many of the students are men advanced in years and hardly *in statu pupillari*, 695–6; the experiments at Cambridge are not made under the control of the authorities, but are performed under the control and direction of one of the professors, 757–61.

The Norwich experiments.

Was in the room when the Norwich experiment of injecting absinthe into the veins of a dog was being tried, but did not learn the nature or object of the experiment until afterwards, 716–7; could not tell whether the animal was suffering or not, it did not appear to suffer much, 707–8; considers that the knowledge that absinthe injected into the veins produces epilepsy, has some bearing on the question of its action when taken into the stomach and is so far valuable, 717–23.

Physiological Handbook.

Does not think the publication of a handbook for the physiological laboratory leads to students trying experiments themselves, 767.

Experiment as to recurrent sensibility.

The sawing through the arches of the vertebræ in demonstrating the existence of recurrent sensibility in the cat or dog referred to therein would be performed under chloroform, 746; the subsequent excitation of the nerve roots would, however, necessarily be performed while the animal was conscious, 747–8; does not think such experiments are described for the purpose of being repeated as demonstrative experiments as it cannot be often necessary to perform them, 747–8.

Experiment described in "The Doctor."

Doubts the veracity of the description in "The Doctor" of an experiment stated to be for the purpose of "demonstrating the structure of the cornea of "a frog by staining the intercellular substance" with lunar caustic, considers the account sensational and the experiment meaningless, 656–7, 662–5. Points out that although pain in a frog is not to be measured by pain in the human subject, 666; this experiment was not tried under anæsthetics, although it apparently might have been, 658–61.

Necessity for Experiment.—Considers experiments on live animals are necessary for the advancement of science, 630; that the advancement of science tends to the relief of human suffering, and that therefore experiments which advance science are justifiable, 778–9.

Development of diseases by civilization.

As civilization which causes diseases increases, the number of experiments necessary will increase rapidly,

Humphry, Professor George M.

especially in pathological subjects, 724; believes that accurate knowledge of the functions and relations of the several parts of the body can only be gained by examining them during life, 602; and that without vivisection our ignorance of the vital processes would be barbarous, 685–8.

Results obtained by Experiments.—Points out that great results are being, and have been attained from experiments on animals, 677; and that animals as well as men are benefited thereby, 683–4.

Nerves of the heart.

Inflammatory processes.

The action of the nervous system on the heart and on the blood vessels, the latter the basis of our knowledge of the processes of inflammation, would not have been dreamed of without vivisection, 603.

The discovery of the passage of the blood corpuscles through the walls of the vessels, could only have been discovered by seeing them so pass and repass in a living animal, 615, 743–5.

Pathological Experiments.—Pathological experiments on animals should to a great extent form the basis of the treatment of scientific knowledge of medicine, 611; admits that many pathological experiments involve pain or distress to the animal, 740–2; which cannot be mitigated to the same extent as in physiological experiments on account of the time, sometimes weeks, which they take, 667–9; many, too, cannot be made under anæsthesia, 615.

Necessity for increase of experiments.

Civilization is the great engenderer of disease and will tend to physical and moral degeneracy unless medical art advances likewise, and therefore pathological experiments become more and more necessary, 635; the number of these investigations is very small, knows only of one or two persons engaged in them, 771; the necessity of a competent operator is even greater than in physiological experiments, 614.

Induction of disease.

The induction of disease in animals is necessary to learn its nature and remedies, 615, with the object of preventing human suffering, it should only be done by competent persons, 634; thinks, however, that disease in animals is not so painful as in man, 616–8.

Inflammatory action.

Action of mercury.

Information as to the causes and treatment of inflammation can only be thoroughly learned by observations more or less painful on the living animal. Believes that by experiments on animals the nature of tubercle is beginning to be understood, even cancer may possibly be one day understood, and be found to be preventable, 615.

Considers observations on the action of drugs and poisons to be a branch of pathology, 698–9; many of the experiments as to the action of drugs on animals are not painful, but anæsthetics can rarely be used, 700–1. Observes that the old notion as to the action of mercury on the liver has been disproved by the experiments on living animals at Edinburgh, 699.

Reasons justifying vivisection.

Limits of Experiment.—Considers that as a large number of animals live by killing other animals it is justifiable for man to inflict death or pain on other animals if there is a reasonable prospect of his being benefited thereby, 599–601; vivisection is often less painful than the ordinary methods of killing, 604.

Wishes what does take place in physiological laboratories were more generally known, there would not then be so much exaggeration and mis-statement, 762.

Difficulty of establishing discoveries.

With regard to the repetition of experiments, points out that the facts ascertained are often of a very complicated nature, and many observations are required to fully confirm them, 635, 680–2; thinks even Sir Charles Bell's experiments on the nerves could hardly render further experiments unnecessary. The results required observation by more than two persons, 636.

Assuming a fact to be established, the experiments demonstrating it should not be repeated except under anæsthetics, 772–3; thinks, however, that there is no definite line between experiments for demonstration and those for investigation, 735, 739.

Physiological education.

Considers that medical students should pass through a physiological laboratory and see some painful experiments; very few, however, would suffice, except in pathology, 736–8.

Vivisection, especially of conscious animals, which is much more difficult, is valueless unless performed and observed by competent persons, 607; when performed by incompetent persons it produces useless suffering, 608, 629, 634; the experiments in which consciousness is necessary are however very few in number, and very seldom necessary, 604–6.

Sensibility of Animals.—Thinks animals do not feel as acutely as human beings, as their nervous systems are relatively much smaller, 641–8; believes that warm blooded animals are more sensitive than cold blooded ones, and man is most so of all creatures, 702–4; points out that a great amount of human pain is in the anticipation and retrospect which is absent in animals, 655; for a similar reason chloroform is more needful in the case of adults than for infants, as is seen, for instance, in the operation for harelip, 704–6.

ances of
cortion
hout
.

Admits that contortion usually implies suffering, but thinks not necessarily so, as the sensory nerve may be destroyed while the motor nerve remains in full action; points out that in epilepsy there is no pain, although there is biting of the tongue and laceration of the muscles, and that there are sometimes violent contortions under chloroform; thinks the contortions of a worm on a hook do not necessarily imply pain, 649–655; in vivisection, especially before chloroform was discovered, has often been surprised by the stillness of the animals under the knife, 707, 710; but admits that absence of pain can hardly be inferred because animals when tied down often do not move under the knife, 711.

sibility
he skin.

erence of
sibilityin
viduals.

Questions whether after the skin has been divided the subsequent pain may be less in animals, but doubts whether the skin in the human subject is the great seat of sensibility, 711–5; believes that sensibility among men differs greatly in individuals, but thinks it more doubtful whether similar differences exist among animals of same species, although a blood horse probably feels more keenly than a cart horse, no one however can be sure, 751–2.

reaso of
section
sequent
heir dis-
ery.

Anæsthetics.—Anæsthetics have been used from the date of their discovery, about 28 years ago, 678; and have facilitated and increased the practice of vivisection, 604; before their discovery experiments were fewer from the reluctance of medical men to inflict pain, 676.

Vivisection both for physiological and pathological experiments can nearly always be performed under anæsthetics, 631–2; has seen many experiments on arterial pressure, but always carried on under anæsthesia, and believes they should always be so performed, 749–50; thinks there is no difficulty in administering them to frogs, 727, although they and the lower animals generally are easily killed by anæsthetics, 731–2; has not, however, had much experience in this direction, 733–4.

Curari.—Is not well acquainted with the effects of curari, 777; and has never experimented with it, but believes it quite possible that the motor action only may be suspended under its influence, and if so it follows that it is not an anæsthetic and frogs under it would suffer, 729.

t to be
formed
students
ept under
ection.

Regulation of Vivisection.—Is of opinion that no experiments on live animals should be allowed to be performed by students except under responsible control and direction, and thinks that a law enforcing this would have the assent of the profession beforehand, 753–6. Has himself, however, more confidence in leaving the limit to which vivisection should be carried to the right feeling of competent men than in legislation, 672.

manity
minent
siolo-
s.

Thinks it is inconceivable that anybody should enter upon such experiments without much forethought and definite ideas as to the points to be elucidated, 618; does not believe they deaden humane feelings, gives instance, 622; and thinks that men of education do not voluntarily inflict pain on animals without good reason, 676; and that the more eminent scientific men would support any reasonable measure for preventing abuses, 609–10; considers that such an experiment as that described in "The Doctor," 656–66, would never have taken place if the matter had been under the control of any eminent man, 673; in any legislation enforcing the use of anæsthetics, pathological experiments must of necessity be excepted, 670–1.

W. PRITCHARD, M.R.C.V.S., F.C.S.

Professor of Anatomy at the Royal Veterinary College.

Has care of the infirmary and performs most of the operations, 780–2; which are entirely for curative purposes, 785. Would not perform an operation unless there were a reasonable hope of cure, 837–8.

approves
erally of
eri-
its.

Veterinary Operations.—No one at all, except the principal, the professor, and the assistant professor, is allowed to operate, 807–11. Students are not allowed to perform even the minor operations with the knife, 839–40; no operations for the sake of experiments are performed, 786; would consider it very improper if there were, 786–7; but admits that if the knowledge derived from an experiment would probably benefit a large number of animals it should be performed, 823.

Navicular disease.

The operation in cases of ulceration of the navicular bone, 881, or navicular disease, consists simply in the division of a nerve, is performed under anæsthesia, gives no subsequent pain and does not interfere with the nutrition of the bone, 873–8. Experiments on healthy horses are not necessary to learn the proper treatment of the disease as it is so frequent; believes half the horses in London suffer from it, 379–80.

Is unaware of any experiments on healthy live animals, but instances novel attempts to cure diseased animals, such as the division of the tendons in the case of a colt with short leg, which was successfully performed, 836–7, under the local influence of ether, 844–5.

Is opposed to physiological laboratories.

Does not say that physiological experiments have no beneficial results; but that the results are not sufficient to trust him to advocate them, especially as direct evidence as to the right remedies is obtainable from treating diseased animals, 882–4. Is therefore adverse to the setting up a physiological laboratory in connection with the Veterinary Institution, believes it would be difficult of control; that needless experiments would be performed, and that the results would not be sufficiently valuable to render it justifiable, 869–71.

Has not seen any physiological researches conducted in any veterinary college; believes abroad a courteous concealment was practised with regard to such experiments, 872. Does not believe that such experiments are performed by veterinary surgeons throughout the country; and believes that if there are, any reasonable law against it would be supported by the authority of the college, 788–90.

Gives details with regard to the working of the College, 783–4, 806–7; knows nothing of the Brown Institution, 834–5.

Sensibility of Animals.—Has performed thousands of operations, and thinks the sensibility in the human and other animals, including frogs, is much the same in all, 846–9. Points out that the irritation produced by a parasite is as great in a small as in a large animal, 850.

Anæsthetics.—Sometimes chloroform, sometimes local anæsthetics, such as ether spray and iced water, are used in operations on animals, 791–3, 889.

Effect of chloroform on horses.

It is almost impossible to destroy horses by chloroform, has had them for hours under its influence, 795; they are however injured by the quantity necessary to produce insensibillty, 804–5; and do not recover so well when it is used, it poisons their blood, 794.

On oxen and sheep.

On dogs.

Oxen and sheep, especially the latter, do not require as much chloroform as horses, 812–4. It is not however safe to apply chloroform to dogs, as the action of the heart is with them intermittent, and they often die, 797–9, 803, 820–2. Would use it on cats, but has had no experience, 800–1.

Curari.—Curari is not now used; believes it was found to produce violent muscular spasmodic contraction, but has no personal knowledge, 816–9. Would not use it himself as there is a doubt as to its being an anæsthetic, 885–7.

Pathological Experiments.—All experiments have been with regard to diseases of animals only, 841.

Inoculation pleuro-pneumonia.

Inoculation has been tried for pleuro-pneumonia, 896; but has not as yet led to a satisfactory result, 906; for small-pox in sheep it is found successful, 904–5.

Foot and mouth disease.

Experiments on healthy animals have been tried with regard to the foot and mouth disease; cannot state the results, but has no hope but they will tend to its cure, 897–900. Was engaged with Professor Varnell in inquiries on behalf of the Government into the cattle plague, and tried many internal and external remedies; such as the injection of opium into the veins, inoculation, &c., but without success, 888, 890–893; the experiments involved little or no extra pain, 894–5. Is not aware of any experiments made with the object of tracing the cause of the disease, 832, although that has been attempted with regard to glanders, 833.

Fluke disease.

Typhoid fever is being induced in pigs to determine a point not ascertainable by other means, 842–3. Experiments with regard to parasites were made by Dr. Cobbold, 829–31. The development of the fluke disease has been watched by causing sheep to take the pupa and destroying them when the disease had advanced, 853–60. Superintended experiments with a view of finding in what animals trichiniæ would live, and how they could be conveyed to the human being, and how this could be prevented. No cure for the disease was found, but much beneficial knowledge as to its prevention was gained, 861–8.

Effects of drugs.

Does not conduct any experiments as to effects of poisons, 851. Believes that something may be learned from the action of drugs on animals as to their probable action on the human frame, but thinks that the results cannot be depended on, 907–10. As the results of experiments on live animals are unfavourable, except as regards determining whether a disease is infectious or contagious, is not in favour of such experiments, with that exception, 901–3.

H. W. ACLAND, M.D., F.R.S.

Regius Professor of Medicine at the University of Oxford, President of the Medical Council, and Fellow of the Royal Society, 911–3.

Is justifiable for the advance of knowledge.

Necessity of Experiment.—Has given attention to this subject from the time of being a student 33 or 34 years ago, and considers that if it is held to be desirable to extend the science of physiology, experiments on live animals are necessary, 915–20. Some of the painful experiments have elucidated points that could be made out in no other way, 922. Is of opinion that putting animals to pain or death is clearly justifiable if benefit to man will result from it, or even if the object is simply to add to the stock of human knowledge, although the question assumes another aspect, 992. Is of opinion that it is impossible to draw a line between knowledge which is, and which is not, likely to be practically beneficial, 993; and that, as in the pursuit of physiological knowledge, experiments must be made, 923, and as medical science is advanced by such experiments, considers they are justifiable, although it is erroneous to say that the progress of science mainly depends upon them, 956–9. Considers that seeing the actual working of the structures of living creatures gives quite another conception of them from studying them in the dead subject; instances the palpitation of the heart of the trout, witnessing which probably led to his own choice of his path in life, 990; and points out that the practical observation of the living structure has revolutionized the old theories of animal economy, 922.

Limits of Experiment.—Approves of the British Association plan of making grants for definite purposes in their experiments, and thinks public grants might be treated analogously, 986, 1003–4; but is of opinion that experiments not calculated to elicit new truths, and not necessary for the education of competent medical men, ought not to be performed, 975; whether such experiments should be forbidden by law is another thing, 975.

Students should be forbidden.

No one but experts should be allowed to attempt or observe such experiments, 927, 947; would not perform them himself, 953–4; and thinks that as students generally will never become experts, they should not perform them, 968. At Oxford students were not, and he believes are not, allowed to perform such experiments, although no particular persons are authorised to perform them, 960–2. Thinks that when the first burst of this knowledge came, 25 or 30 years ago, students were not wrong in verifying observations by actual experiment; joined in many for this purpose himself, 927.

Except under great necessity, would not perform a painful experiment except under anæsthesia, 966; and has a horror of dissection, although he has done a great deal, 989.

Painful but necessary experiments.

The larger number of experiments which have added to our knowledge were performed without anæsthetics, many indeed took place before their discovery, 921. Many of the experiments relating to the nervous system, circulation of the blood and structure, were very severe and painful; nevertheless, men of tender and gentle natures, such as Sir B. Brodie, Dr. Hope, and others, performed them, because no other means of solving the question at issue was available, 921, 926. Men like Hunter, Brodie, and Davey seem to have an instinct which restrained them from unsuccessful experiments; inferior minds do not seize the precise points where further development is possible, and hence much useless suffering is thereby caused, 1005–7. Some of the experiments of Sir B. Brodie, &c., were on animals just killed, rather than on live animals, 921. It is not certain whether observations on live or dead subjects led Harvey to his great discovery, 991. Thinks that the experiments of able men, like Dr. Klein, although fruitless as regards mitigating human pain, may advance knowledge, 1008. Cannot give an opinion as to Brodie's experiments with regard to the nerves influencing digestion; but points out that deciding that no further advance is possible is itself a gain, 1005. Painful experiments which have established a fact should not be repeated, unless it should subsequently appear that the conditions under which they were performed were of a nature to modify the result, 924–5, 987.

No experiments on live animals should be allowed for demonstration.

Dragging out the mesentery of a frog, although very painful, may not have been cruel in the first person who did it; but repeating the experiment, when the result is known beforehand, is both cruel and useless, 922–3. For the purpose of demonstration witness performed a series of experiments to show the development of the mammiferous ovum, involving the deaths of animals, but not their vivisection, 988–9; but thinks there is much less need than formerly for experiments by way of demonstration, 988. Goes further than the resolution of the British Association, saying that "painful experiments" should not be used for demonstration; thinks no experiments on live animals should be performed for this purpose, 947; thinks it wrong to make a common practice of sacrificing the life of a rabbit, even painlessly, for purposes of demonstrating things which could be learned from diagrams or dissections, 933, 989; has himself furnished hundreds to prevent the necessity of repetition, 947; these dissections were prepared from dead animals, sometimes killed for the purpose, 964–5.

On the other hand many experiments are painless, as for instance the observation of the circulation of the blood in the transparent texture of a frog's foot, 922.

Change in the motive for investigation.

Extent of the Practice of Vivisection.—The Royal Society's Transactions and other scientific publications are full of accounts of such experiments from the time of Harvey downwards, 986; and the Royal Society awarded the Copley medal to Sir Benjamin Brodie for his experiments on live animals, 985. The improvement of the microscope about 30 years ago gave a great impulse to experiments, 922. Points out that formerly scientific research was in the hands of medical practitioners only, but that now the extent of knowledge has been so vast that the field has become subdivided, and professed physiologists have arisen whose sole object it is to advance knowledge, 981–2; formerly the first object sought was new methods of alleviating human suffering, 983–4.

Physiological laboratories were the outcome of the zeal of the physiological teachers, and of the general desire for increased and more perfect appliances in all branches of the sciences, 978, 980.

Thinks there is an increasing number of biological students who study anatomy and physiology in the pursuit of abstract knowledge, rather than as medical men do, with object of discovering remedies and mitigating human suffering, 944.

A desire for pure research, irrespective of ulterior benefits received therefrom, is now spreading over Europe, and it may be feared that a practice has arisen with it of dealing with animal organisms much in the same way as if they were unconscious inorganic substances, 944–5.

Disregard of suffering.

Has not recently been much in foreign laboratories, but believes the use of chloroform is habitually neglected, 941; and that a great deal is being done on the continent which would shock the feelings of this country and not be tolerated here, 946; the extent to which these experiments are carried abroad is much greater than here. Considers the tendency of one phrase of modern thought is to treat living organisms simply as forms of matter which it is desirable to investigate, 999; and the consequent disregard of suffering in these experiments touches on very serious ground, 999.

Dr. Sanderson's Handbook.

Dr. Sanderson's Handbook for the Physiological Laboratory appears designed to explain to learners how to pursue these experiments themselves, 970–1, 999.

Physiological education.

The General Medical Council has the supervision of medical education, 976–7; and the question of requiring practical experimentation from students will doubtless come before it when the whole plan of medical examination and education is considered, 967, 979; this would have been done during the present year had not the Commission been appointed, 951.

Brown-Séquard.

Pathological Experiments.—Thinks that although Brown-Séquard had 584 guinea pigs under experiment at the same time and had had in the course of 30 years very many thousands in his laboratory, that public opinion might deal with the much larger amount of needless suffering caused by field sports and what are called innocent amusements, 944–5; experiments on the scale of Brown-Séquard's would be liable to abuse in the hands of inferior men and would be useless, 997. Refers to the researches made by artificially producing tubercle in animals, and the remarkable discovery of

Brown-Séquard's as to the possibility of producing epilepsy in pigs and of rendering it hereditary. Adverts to the possible beneficial results of such experiments, and deprecates the censure of any but those specially acquainted with the facts, 952.

Anæsthetics should be used whenever possible, 938–9; nearly all necessary experiments can now be performed under their influence, 932–7; agrees on the whole with resolutions of the Committee of the British Association, but is almost ashamed to have to formally assent to such an obvious proposition as that all experiments that can be performed under anæsthetics should be, 947.

Cannot say whether curari destroys sensibility, 973; there are some niceties about its use, its effect is to destroy voluntary motion, 972; and for this purpose it is used in the experiment in which the mesentery of a frog is laid bare for observing the circulation of the blood, 972–4.

Regulation of Vivisection.—Whether control should be exercised by law or by the Royal Society or some scientific body is a question which witness feels it his duty to leave to the Commission, 1002–3; thinks that legislation might restrain incompetent persons from performing such experiments, 930; but is not prepared to say that observations for scientific purposes should be under ordinary legislation, 928; and is unwilling to think that such a course is necessary, 929.

precates
islative
triction
compe-
t person.

Does not consider the control exercised under the Anatomy Acts analogous, 1000–1.

Is of opinion that the competent men in England are to be trusted, 969; that the general tone of scientific feeling is good with regard to these experiments, and that abuses must be very rare, 998; believes that in the great schools the control and discretion of the professors is sufficient safeguard against abuses, 930–1.

Thinks that the habitual performance of experiments without chloroform would not be possible in any English operating theatre, the good feeling of the profession and of the public would make it impossible, 940–4; if wanton cruelty is proved against teachers it should be put down, 1002; supposing that it exists among students it could be punished under the Cruelty to Animals Act, and thinks that if it occurred in schools the schools should be suppressed, 949–50.

ntinuous
uses not
ssible in
gland.

Does not believe the scientific men of England are regardless of suffering; if it is proved that they are, they deserve the humiliation of having a legal enactment levelled against them, 948.

SIR WM. FERGUSSON, BART., F.R.S.

Sergeant Surgeon to the Queen, Surgeon of King's College Hospital, and Fellow of the Royal Society 1009–11.

In early life had a great deal of experience in experiments on live animals, but not much latterly, 1012–4; witness' opinion of these experiments is much less favourable now than formerly; would not now perform many of the experiments he did then, 1031.

Results obtained by Experiment.—Considers that although these experiments have been of great service, their value has been altogether exaggerated, 1015, 1032, 1117; and that they often give fallacious results from the introduction of abnormal conditions both by the use of the anæsthetic and by the disturbance caused by the operation, 1085.

lvantages
sulting are
eatly ex-
gerated.

Admits that the knowledge of the circulation of the blood and of the nature of the actions of the heart, liver, kidneys, and nerves was ascertained or increased by these experiments, but doubts the value of knowledge thus obtained, seeing the observation could not be made on these organs in their normal condition, 1051–3; but thinks many of the most striking experiments are performed on the lower animals *after* they have been tried successfully on the human subject. Hunter's discovery of the practicability of tying the arteries, 1024–5, some of Sir Astley Cooper's operations and Sir James Simpson's experiments with chloroform, 1033–4, were performed first on the human subject, 1026; believes that all surgical operations without exception were first tried on human beings, 1092–3; is not aware of any experiment which has led to the mitigation of pain or improvement of method in surgical cases, 1032, 1049; indeed more experiments are performed by those who are not practical surgeons than by those who are, 1033.

ents.

Thinks the experiments referred to by Sir J. Paget are not of the smallest practical value with regard to the transfusion of blood in human beings, 1104–5; doubts whether Mr. Syme's operation as to the life and death of bone had much beneficial influence, 1027; their object, however, was physiological rather than surgical, 1030; subsequently Mr. Syme was strongly opposed to operations on animals, "unless for the purpose of causation"; reads extract from the "Veterinarian" to that effect, 1027–30; considers this, the mature opinion of such a man, of very great weight, 1039; admits that Mr. Jones' experiments with regard to the best sort of ligature were valuable, but there remains as much doubt now as then in spite of experience and Mr. Lister's experiments at Edinburgh, 1094–9, 1108–9.

Mr. Syme's experiments, and subsequent disapproval of them.

Ligatures.

Considers that the practice of medicine is based upon clinical and pathological rather than physiological observations, 1102–3; is himself guided by the result of his observations on the human subject, and does not think he has gained any increase of knowledge from these experiments, 1100–1.

Extent of Practice of Vivisection.—Is impressed by the fact that the taste for this sort of investigation is on the increase, 1016; as is shown by the provisions made for it in the new University Buildings in Edinburgh, 1115; doubts, however, whether the gain to knowledge has been commensurate, 1017; believes that painful experiments are more numerous than necessity warrants, 1018; and that there is much useless repetition; when a fact has been established, the experiments demonstrating it should not be repeated, 1019; unless some new element comes under view, 1020–1; and even then great judgment is necessary, and the number of persons fit to perform such experiments is limited, 1022–3.

Experiments are over numerous;

Believes many experiments are performed in a most reckless manner, 1035; even in the London laboratories, judging from what he is told by students; thinks inquiries should be made with regard to them, 1112–6, of the younger members of the profession or senior students, 1125.

and recklessly performed;

Fears that experiments even in England are protracted in a very shocking manner; instances the case of an animal kept crucified for many days together and brought many times into a class room, 1037–9.

and often needlessly protracted.

Believes that if the manner of conducting these experiments were fully known, the reputation of certain eminent scientific men would be greatly lessened, 1036; and as much public indignation aroused as there was formerly with regard to body snatching, 1040, 1048.

If details were known great indignation would be aroused.

Although many eminent English surgeons have very legitimately performed various experiments on animals for the elucidation of definite points, 1091, they have not been extensive experimenters in this way, 1026.

Legitimate experiments.

Operations on animals are not practised in England to acquire dexterity; thinks such a course would be useless, the circumstances are so different, 1087–90; is not aware of anyone who has become an expert by this means, 1026.

Surgical dexterity not acquireable thereby

Believes there are very few amateur physiologists in England, 1139; and that very little physiological work is done outside the great schools of physiology, 1139; if unnecessary cruelty exists in them a remedy is necessary, 1140.

Private experiments.

In the Norwich experiments the dogs, witness is informed, were kept strapped down to boards; the straps, however, were cut by a surgeon to give them some kind of relief, 1086; is happy to say he did not witness them, and thinks they were founded on altogether incorrect views, 1106–7.

The Norwich experiments based on incorrect views.

Has purposely avoided Dr. Sanderson's Handbook, but believes it describes a large number of experiments which ought not to be allowed, 1110–1.

Dr. Sanderson's Handbook.

Anæsthetics.—Attaches very little value to experiments under anæsthesia, because an animal is no longer itself under such abnormal conditions, 1077–83, 1085.

Experiments such as those relating to the discovery of the circulation of the blood, are not however open to this objection, 1084.

Anæsthetics alter the conditions and vitiate results.

Curari.—Knows that curari is a poison, but is not aware of anything tending to show that it is an anæsthetic; believes it has never been tried on the human subject, 1071–6; and very much doubts that it makes animals insensible, 1077.

Regulation of Vivisection.—Considers a remedy for existing abuses desirable, but it is very difficult to point one out, 1046–7; the subject is more difficult of regulation than dissecting. Scientific men should not be trammeled, but enthusiasts should be restrained within

Licences.

bounds, 1045. Thinks the appointment of an officer to attend all these experiments would be offensive to all scientific men, 1058, and the plan of granting licences for these experiments of questionable policy, 1060–1.

Force of public opinion better than legislation.

But a formal opinion should be expressed by the legislature.

Would leave the control of these experiments to the influence of public opinion rather than legislation, 1055; considers that the greater humanity of treatment existing in English hospitals is due to the operation of public opinion, 1056; thinks Government could only interfere by recommending carefulness to scientific men with regard to performing such experiments, 1041, 1054, 1057; but believes that the expression of the views of the Houses of Parliament or of Government would result in a man's losing caste by going beyond certain bounds, 1041–3, 1062–3; and thinks therefore that it would suffice that the Commission should strongly express their views on the subject, and leave the rest to public opinion, 1059; which would be a sufficient check. Men would avoid gaining a reputation for indifference to animal suffering, 1118–9.

Facts should be made known.

Public opinion and Society for Suppression of Cruelty to Animals would be sufficient check.

Admits that at present the public is not informed as to what experiments are taking place, and that public opinion cannot therefore be now brought to bear on them. Thinks this should be obviated by some change of the law, and that then the force of public opinion, coupled with an expression of opinion on the part of the Government, and supplemented by the action of the Society for the Suppression of Cruelty to Animals, and the restraints of the present law would suffice, 1120–35.

Governors of Hospitals.

Thinks that the attention of the governors of hospitals should also be drawn to the matter, in order that some of their number might be appointed to prevent unnecessary cruelty, 1138.

Private experiments would be reached by public opinion.

Ignorant operators.

Is aware that many of these experiments are performed in private houses, but believes the experimenters would be reached by public opinion in the long run, even if not by the Society for Suppressing Cruelty to Animals, 1064–6; many private experimenters are very talented men, and should not be interfered with unless they were found to perform unnecessarily cruel experiments, 1141; any excess of cruelty on the part of ignorant experimenters should be punished, but fears lest quacks and bone-setters would thereby come to be martyrs in popular estimation, 1136–7.

Record of experiments should be kept.

Inspectors of physiology.

In any legislation it would be very desirable to provide for a record of all experiments being kept, just as is done with such strictness and great advantage as regard subjects for dissection, 1044, 1142–4; provided the Commission finds that these practices were carried to an exorbitant extent, 1147–8; believes it quite possible that the appointment of an inspector of these experiments, having analogous duties to the present inspector of anatomy, would be desirable, 1145.

Amendment of Cruelty to Animals Act.

Thinks it would be highly desirable to include "wild" as well as "domestic" animals under the Cruelty to Animals Act, 1066–9; does not think the argument that this course might apparently tend to stop field sports of any weight, 1070.

ALFRED SWAINE TAYLOR, M.D., F.R.S.

Fellow of the Royal College of Physicians, and for 44 years lecturer on medical jurisprudence and toxicology at Guy's Hospital, 1148–9.

Is the author of a work on poisons and medical jurisprudence which is often referred to in the courts of law, 1150; has performed about 12 or 14 experiments on living animals in 40 years, 1151, 1266; sometimes using the knife to make a slight wound in which to insert the poison, 1152–3; and has in other ways experimented largely in toxicology, 1154.

There is a practical class at Guy's for the chemical examination of poisons; arsenic has been occasionally given to rabbits; but no experiments are performed by students, 1233–5.

Medico-legal Experiments.—Has been employed by the Government in all the great cases of poisoning during the last 20 years, including Palmer's and Smethurst's cases, 1155.

Palmer's case.

In Palmer's case witness and Dr. Rees experimented on six rabbits, and proved that an animal might be killed by a quantity of poison received by absorption, so small that it could not be detected, and that the possibility of discovering poison depended on the time the animal lived after taking it, 1157; one medical witness for the defence experimented on 60 animals, 1165–6; apparently with the object of ascertaining under what circumstances poison could and could not be detected

in the viscera, gives details of the special difficulties on the point in Palmer's case, 1167; no additional knowledge was gained by these wholesale experiments, but it was argued that the four or six cases in which the poison could not be found should not avail against the 100 or so in which it was found, 1168.

Cobra poison.

Instances a physiological experiment performed by himself with regard to the poison of the cobra di capello proving that after having been kept in a dry state for 12 years it had not lost its power, and that it operates by absorption through a wound but not through the stomach, the latter having been a moot point previously, 1160–1.

External arsenical poisoning.

Instances the case of a woman who applied arsenic in an ointment to the child's head for ringworm; the child died and arsenic was found in the stomach. Dr. Pavy and witness found on experimenting with rabbits and dogs that arsenic received into the system externally found its way into the stomach if the animal lived a few hours, a scientific fact not clearly proved before. The child in question was found to have lived two days after the application of the ointment, and in the end a verdict of accidental death was recorded, 1162; thinks this result was a justification for these experiments, 1163; and that such experiments are often productive of benefit, 1164; although as in Palmer's they are sometimes conducted on an unjustifiable scale, 1165–6.

Tawell's case.

In Tawell's case prussic acid was the poison, the action of which is known; there were therefore a few experiments only, 1200–1.

Necessity of Experiment.—Experiments are useful for the discovery of antidotes, 1203; and as new drugs are continually being found, they are necessary for discovering their properties, 1188. Again, when chemistry fails to detect a poison it may be necessary to apply part of the substance said to have produced death to a living animal; gives instance, 1188. In these experiments it is found that the quantities of poison which will kill a dog or a human being, and also the symptoms and effects are much the same, 1202; points out that although the effects of a drug on small birds and frogs may prove it to be a poison, it does not give much information else, 1171–2.

Dogs.

Extent of the Practice of Experiment.—Neither at Guy's nor elsewhere in England is there any reckless toxicological experimentation, except possibly in connection with great trials; the great number of experiments are in France and Germany, 1235–7. Believes that English scientific men perform these experiments only to obtain actual benefits, and that they would support any legislation for restraining it with these limits, 1184; for a particular experiment rarely more than one animal would be necessary, 1263–5; and in England the total number so destroyed is not large, 1267.

Not abused in England,

except in criminal trials.

Believes, however, that these experiments are resorted to more often than is necessary; they were especially so in Palmer's case, 1158, 1195–9; thinks this objectionable in itself, and also because a jury might be influenced by the mere number of experiments; in the interest of science would not however approve of any legislative limitation, 1213–6.

French experiments often useless and cruel.

Many evidently useless painful experiments are performed, especially by French experimenters, 1178. Instances some hundreds of experiments performed by a very eminent French physiologist on dogs with all manner of poisons, which were useless because he introduced a non-natural condition by cutting into the neck and tying the æsophagus to prevent vomiting, 1171. Has studied in Paris; believes experiments are very numerous there, and that at Alfort they are carried out on a very cruel scale, 1269.

Repetition of experiments.

When a thing is once proved repetition is useless, 1169; and many experiments, even by eminent men, have no useful result, 1170; does not think the publicity given to discoveries much affects the number of experiments, 1212.

Experiments for demonstration unnecessary.

Experiment for the sake of demonstrating the known action of poisons, instances strychnine, is purposeless cruelty; has never performed such experiments himself, 1179–80, 1260; with the exception of one or two with regard to the action of the mineral acids, 1227; but as the students did not gain more from these experiments than they did from the drawings and models he discontinued them, 1261.

Considers verbal description, supplemented by coloured wax models of the stomachs of human beings and dogs and by drawings, is sufficient to enable students to recognise the action of ordinary poisons, 1223–7, 1261–2. Has also a large number of stomachs of human beings

Taylor, Alfred Swaine, M.D., F.R.S.

who have been poisoned; uses them for demonstration, 1228.

Cannot remember any instance where the death of an animal is necessary in medico-legal teaching, 1229; the only operation necessary is the slight puncture required to get fresh blood, 1230–1.

Anæsthetics.—Has not heard much of anæsthetics being used in toxicological experiments, 1241; they would render it impossible to rely on results, 1189–90. In many cases too nervous activity is essential; protracted suffering is never, however, necessary, and the animal should be destroyed directly the object had been attained, 1181-3.

Curari.—Believes curari to be a sedative, 1238; and that it acts upon the muscles through the nerves; has never heard of any recovery from poisoning by it, 1191–4. It is commonly used in physiological laboratories in England, 1240. Would not himself use it as an anæsthetic, 1242–3; but thinks the diversity of opinion with regard to it arises from variations in the preparation, 1239. The alkaloid curarina appears to destroy sensation, but it is hardly obtainable; it acts as a poison, but too little is known of it to warrant its general use, 1244–7. The sedative action of curari is said to afford a remedy for the excessive stimulus produced by strychnia, 1204.

Curarina.

Dr. Sanderson's Handbook.

Dr. Sanderson's Handbook is a book of very considerable reputation, 1270; thinks the application of nitrate of silver to the cornea of a frog, in order to produce inflammation, would not be very painful, 1256–7; considers putting a frog, a cold-blooded animal, into water and gradually raising the temperature to 100° Fahrenheit equivalent to boiling it alive, and that it would be a cruel and apparently purposeless experiment, 1258–9. The extraction of the mesentery of the frog for observation, referred to in Dr. Sanderson's Handbook, must be a very painful experiment, and witness cannot see what object it can serve, 1271.

Boiling a frog alive.

Extracting the mesentery of a live frog.

Norwich experiments.

Considers the Norwich experiments were most cruel and unjustifiable, 1188.

Chronic poisoning.

Chronic poisoning is rare, and has only occurred when the criminal has some medical knowledge, 1207; thinks it desirable that the knowledge of the action of poisons, which cannot be detected chemically, should be confined to the profession, 1208–11.

Strychnine.

Strychnine is a spinal poison and kills all vertebrate animals, but not the invertebrate; gives instance, 1174. It was not made known before the trial of Palmer, although a case of poisoning by it occurred in 1831, when the symptoms were set down to tetanus, 1220–1. Thinks it is quite unnecessary to illustrate its action by experiment, it can be accurately described; there is something dreadful in its operation, 1218–9, 1222.

Prussic acid.

Placing a dog under a tap of cold water has been found to restore it when poisoned by prussic acid, and a similar course has been found useful with human beings, 1204.

Snake poison.

Considers the discovery of an antidote for snake poisoning unlikely, as it takes effect so rapidly and could only be combatted by some substance at once entering the blood, 1205.

Sensibility of animals.

Thinks that the sensibility of frogs and other anirnals varies in proportion to the perfection of their nervous system, and that the excitement of the motor nerves does not necessarily imply the existence of pain, 1554–5.

Exemption of certain animals from experiment.

Regulation of Experiments.—Thinks that any law should define the classes of animals that were not to be experimented upon except under restriction, and that some competent person should be appointed to assist the magistrates in deciding whether a given experiment were necessary, 1185; a point which requires much scientific knowledge, 1175–8.

Licence system.

Is inclined to approve of the suggestion that licences should be granted to fit persons to perform these experiments, but a great deal must in any case be left to scientific men, 1186, who are as a rule humane, 1187.

Licensed laboratories.

Thinks that the performance of toxicological experiments might be confined to certain licensed laboratories, except in cases where despatch would be necessary and which might be specially provided for, 1248–53.

GEORGE ROLLESTON, M.D.

Linacre Professor of Anatomy and Physiology at Oxford, 1272, 1333.

Is a member of the committee, formed by representatives from the Universities and the Colleges of Physcians and Surgeons, for the purpose of preparing a conjoint scheme for medical examination, 1274–5.

Rolleston, George, M.D.

Witness' own experiments have been on a very limited scale, being quite as much an instructor of ordinary English gentlemen as of young doctors, 1342–3.

Resolutions of the British Association.

Drafted the resolutions passed by the British Association at Edinburgh, 1273, separating experiments for investigation from experiments for demonstration, and insisting that the latter if performed should be made under anæsthesia, 1278; wishes they had also required animals to be killed before awaking to consciousness, 1276–7.

Results obtained by Experiment.—Admits that it is one only among many means of gaining knowledge, 1280; but considers that it has thrown great light on those terrible diseases diabetes and epilepsy, 1280, although a remedy may not yet have been discovered for them, 1302; and that the possibility of tying an artery without starving the limb is another instance of its usefulness, 1280.

Diabetes and epilepsy.

Tying arteries.

Action of poisons.

Necessity for Experiment.—Testing the action of poisons on animals sometimes, as in Palmer's case, necessary, 1280; as it might also be if a man died after eating some particular substance the nature of which was not known, 1280. Points out that the effects of a drug on animals is no certain guide to its effects on man; a rabbit will eat enough belladonna to poison a dozen men without injury, 1280.

Effect on animals not a certain guide.

Belladonna.

In Ireland.

Extent of the Practice of Vivisection.—In the Irish School of Physic vivisections for teaching purposes are strictly prohibited, 1286. In the recommendations of the committee for forming a uniportal system of examination and in the bill introduced by Sir John Lubbock actual vivisection is expressly excepted from the subjects to be required from students, 1275, 1283; those intending to become physiological investigators might, however, practise it, 1284–5.

Sir John Lubbock's bill.

At Oxford.

No student is allowed to experiment in the University Museum at Oxford, nor is there any reckless experimentation there, 1334–5; does not show students going in for examination experiments upon live animals at all, but a few under anæsthetics to those who graduate in arts through a science curriculum, 1336–7.

Professor Schiff.

In Professor Schiff's work almost every lecture is accompanied by the sacrifice of some animal; 700 a year, it is stated, thus perish, 1343. Calls attention to a discrepancy between two statements of Professor Schiff, one stating that the dogs made no noise because they were not in pain, the other stating that their nerves of vocalization had been cut "*pour les empêcher* * * "*de discréditer ainsi les études physiologiques auprès* "*des habitants du quartier*," 1287.

Private experimentation.

Knows that private experimentation exists, but cannot say to what extent it is carried on, 1332. Doubts how far it can be brought under control, 1291–2, 1301. It should not be forbidden, and would be controlled indirectly by the restraints placed on public experiments, 1303–5, 1330.

Causes tending to produce abuse of practice.

Limits of Experiment.—Considers these experiments are very liable to abuse, investigators are carried away by the absorbing nature of their researches, 1286–7; and that lecturers are under considerable temptation to show off their skill in these experiments. Argues with Mr. Skey that "a splendid operator is ever a just object of suspicion," 1287.

Thinks the desire of impressing facts on the mind through the medium of the sight sometimes leads to extravagance in experimentation, 1286; thinks the practice of vivisection is abused just like that of taking alcohol, but does not think therefore it should be forbidden, but considers that it should be controlled, and that the number of experiments might be much diminished without injury to science, 1293.

Address to section of British Association in 1863 on vivisection.

Reads extract from the Transactions of the Biological section of the British Association for 1863, containing the gist of witness's address on vivisection, pointing out that sensibility was usually extinguished more speedily by the physiologist than by the butcher or sportsman, and that valuable knowledge had been gained by these experiments with regard to epilepsy and diabetes, but that they could not be justified when performed for the sake of acquiring operative dexterity only, 1273.

Effects of experiments before a large number of men.

Believes that painful demonstrations are demoralising, 1299–300; especially when performed before large numbers, and that they act on the emotions-motor nature and wake "the sleeping devil in the hearts" of men. Quotes Kingsley and Lipsius in support of this, 1287, 1338. Considers therefore that such experiments should be performed before a very limited number of individuals only, 1279, 1308–11; and should be subject to regulation, 1313. Thinks painful experiments for demonstration to students should be forbidden, 1306–7, 1309, 1314; a few cardinal experiments, however, may be desirable to enable students to appreciate records of other experiments, provided anæsthetics be used and the experiments be such as cannot be otherwise demonstrated, 1283, 1291, 1294–5; and that the animals were always killed before recovering from the anæsthetic, 1315–6.

Painful experiments not allowable in teaching.

Very few painless ones are necessary.

Uncertainty of effect.

Anæsthetics.—The whole question of anæsthetizing animals has an element of uncertainty about it, 1350; it is not easy to know when an animal is anæsthetized, and there is a great difference with regard to the duration of its effects on different individuals of the same species, 1349. Is inclined to think that a large dose of curari acts as an anæsthetic, 1350.

Curari.

Dr. Sanderson's Handbook of Physiology.—With regard to the portion contributed by Dr. Michael Foster, points out that experiments may be trusted to such men which would not be rightly left to the ordinary physiologist, 1344; admits that the experiments are obviously described for the purpose of being performed, 1346–9. A frog killed by placing it in water and raising the temperature to 100° Fahrenheit, would not be "boiled or blistered," as albumen either in the frog or in the human being does not coagulate under 140° Fahrenheit; thinks, however, such an experiment should not be repeated, 1345–6; in the experiments described, the frogs are in many cases pithed, in others put under the action of curari only, 1352–4; is sorry to have to say that he thinks the handbook to a great extent warrants the present public feeling on the matter, and regrets that it is likely to represent its authors as something other than one at least, Dr. Foster, is, 1351.

"Boiling" a frog alive.

Effects of the handbook.

Is of opinion that there is, in spite of a downward tendency during the last year or two, 1339, a growth of moral sentiment in the human race generally tending towards greater carefulness in the infliction of pain, and that a similar development takes place in individual minds; quotes the "Philosophical Transactions" of 1667, and "Spectator" of 1874 in support of the general proposition, and refers, with regard to individuals, to Haller, who in his latter years fell into a "permanent anguish of conscience" at having vivisected to such an extent as he had, 1290; a man in his maturer years will condemn what he did in his youth, a child will pull off a fly's wings without remorse, a man would think it extreme cruelty, 1296–7; thinks therefore that society may rightly control the individual, 1298.

Popular feeling is growing more humane;

and individual feeling becomes more so in mature years.

Regulation of Experimentation.—Quotes opinion of Dr. Child that legislative interference, which was not necessary 10 years ago, is now required, the inclination to resort to experiment being now so much greater, 1340–1.

Public laboratories.

Thinks very little inconvenience would be caused by forbidding experiments to be performed except in public laboratories; experiments necessary in poisoning cases, however, should be exempted, although generally these even might be sent to a public laboratory, and be performed there by experts, 1327–9, 1331; with regard to private experiments, is inclined to say "*de minimis non curat lex*," 1323–6; thinks an inspector of physiological laboratories, with duties analogous to those of inspectors of anatomy, would probably be beneficial, 1319–22, 1324; and that a record of all experiments made and the reasons for making them should be kept, 1317–8.

Inspectors of laboratories.

JOHN SIMON, M.R.C.S., F.R.S.

Medical Officer of the Privy Council and Local Government Board, 1354–5.

Has been engaged in various pathological investigations, 1356–7, 1396; but, with the exception of some experiments on the inoculation of tubercle in 1866 or 1867, has not recently performed experiments himself, 1472; has also for many years been surgeon to St. Thomas' Hospital, 1440; and has been connected with the hospital for about 42 years, 1450–3.

Necessity and Results of Experimentation.—Justifies experiments on animals on the ground that by them the causes of diseases are found out, and that this is the first step towards preventing them, 1409, 1358; the physiologist seeks to discover facts, and these may, and often do, render improved treatment possible, 1462; the knowledge obtained by the physiologist is used by the general practitioner, 1460–1.

Ligature of arteries.

Mr. Jones' experiments in connection with the ligature of arteries are the foundation on which the present practice rests, 1446–7. Hunter himself lost patients from want of knowledge on this point, 1448–9. The knowledge of the nature of inflammation and of fever derived by experiment is so important that witness relies upon it in preference to that obtained from other sources, 1443.

Discovery as to nature of inflammation and fever.

Believes that experiments on animals have tended immensely to the advancement of surgical science, 1442; and that those eminent men who have considered the subject will concur in saying that these experiments are necessary, but should be conducted with all possible regard to humanity, 1368.

Medicine and surgery are based on clinical observation, physiological research, and experimentation, 1444–5; and experiments on animals obviate much needless experiment on man, 1442; wishes to rest the case for these experiments on the general basis that exact knowledge is the foundation of preventive or curative treatment, and is therefore most desirable, whether an immediate benefit follow or not, 1417, 1420–1.

The advancement of knowledge sufficient justification for these experiments.

Puts in a pamphlet on vivisection, written he believes under a pseudonym, by a man of eminence, 1511–4.

Government Investigations.—There is an annual grant of 2,000*l.* made by Government for medical scientific investigation, one half of which goes to aid investigations in which pathological experiments on animals are sometimes necessary, 1360–2; a great many of these are on the dead subject, 1363–4.

Grant for investigation.

Reads an official note by Mr. Forster recording his opinion that experiments made at the cost of the state should only be performed, if painful, under anæsthetics, and that a record should be kept of each, stating its aim and the necessity for it, 1367; this minute was referred to Dr. Sanderson "to read and note as an instruction," 1511.

Mr. Forster's instructions

Reads his own official report setting forth that these experiments are sometimes necessary to obtain exact information as to the causes of disease, as for instance those with regard to cholera, sheep-pox, and cattle plague; that they are sometimes necessary to test the value of alleged remedies; that they often are attended with little or no pain beyond that of the disease; that animals should be destroyed when the object of the experiment had been obtained; that anæsthetics should be used when possible, and that the experiments performed on behalf of the Government had been strictly confined within these limits, and only undertaken with the object of obtaining knowledge beneficial to humanity, 1367.

Objects of official investigation.

Dr. Sanderson, Dr. Klein, Dr. Creighton, and Dr. Baxter have been the investigators, 1473–4; and among the chief subjects which have been studied are cholera, tubercle, præmia, sheep-pox, and disinfectants, 1359.

In the experiments to test the infectability of animals by choleraic discharges, mice were generally the animals selected, the only pain was that caused by the disease induced, 1364–5.

Cholera.

By experiments on animals, consumption is found to be inoculable; points out the emphasis this lends to certain observed instances of apparent infection in human beings, 1420–4.

Consumption.

Admits that no improvement of treatment has resulted from the experiments with regard to sheep-pox, but believes the increased knowledge of the contagion of the disease will result in rendering prevention easier, 1417–9; thinks it probable that there is considerable pain with the sheep-pox, 1431; but the inoculated disease is usually very mild, and after temporary inconvenience and distress the animal would usually recover, 1432–6.

Sheep-pox.

Valuable experiments have been recently made with regard to disinfectants, the results of which will probably form the basis of the advice given to the public for years to come, 1474.

Disinfectants.

Typhoid fever is a form of blood poisoning, but has not been artificially produced by them, 1470–1; scientific results intimately related to practice have been obtained by experiment in pyæmia; intends shortly to publish some which will be in print, 1465, 1469; the duration of very painful experiments would be reckoned in hours, 1466–8.

Typhoid fever.

Pyæmia.

Is now making investigations, but not on animals, who do not appear to be liable to it, with regard to scarlet fever, in the hope of obtaining a knowledge of its causes and of so preventing its spread, 1425–9.

Scarlet fever.

Admits that pathological experiments sometimes give fallacious results, but believes every effort is made to guard against it, 1482.

In the Government investigations witness has never had to perform a severe surgical operation, and in linger-

eports are
ade on
ach series
f experi-
ents.

ing diseases the animals are put out of pain as soon as possible, 1430, 1438–9. Reports are made on all experiments performed; the number and kind of animals operated on are generally mentioned, as well as the objects of the experiments, 1397–405.

Puts in a return showing the investigation made during the last four years, 1368, 1398.

dvice by
overnment
ased on
esult of ex-
periments.

Considers that the advice that the Government was enabled to give the public with regard to preventing the spread of cholera by keeping water pure from the slightest taint of choleraic excrement, was entirely arrived at by experiments on animals, although other facts pointed in the same direction, 1406–16.

Extent of Practice of Vivisection.—Thinks the practice is confined in England to a few competent persons, 1369–71; does not believe that these experiments are recklessly undertaken or performed by any appreciable number of persons, 1378–81.

Past and
present
extent of
practice.

Believes the number of painful experiments has relatively and probably actually diminished since the time of Majendie; doubts whether any one in England now performs severely painful operations on the same scale as Mayo did then, 1372–3, 1478–80; has not, however, been working in this direction of late years, and therefore speaks with reserve, 1437.

Most eminent surgeons have been experimenters on animals when definite points required investigating, those who have not were probably experimenters on their human patients, 1459.

Is not aware that experimental physiology has lately been recommended as a study for all medical students, 1494.

Experiments on
frogs.

Students at Guy's Hospital do not perform experiments on living animals, 1451–2; although advanced students probably occasionally use frogs for observations causing pain, 1495; foreign frogs are preferable to English frogs for some physiological purposes, 1496; the use of anæsthetics is general with regard to domestic animals, but not with frogs, 1498; has difficulty in comparing the sensibility of frogs to pain with that of other animals, but does not doubt their full susceptibility to pain, 1499.

Sensibility
of frogs.

Pain rarely
necessary.

Limits of Experimentation.—Believes that it would rarely be necessary for an animal to be sensible to pain during a severe operation, general or local anæsthesia is nearly always possible, 1374–7; considers that great pain may be necessary to achieve a great result, but that it is not justifiable for small results, 1483–4; much must be left to the individual conscience; it may be desirable that the scientific conscience should be influenced by the conscience of the educated public, but certainly not by that of the mob, 1485–7; if abuses exist, scientific men would concur in supporting a remedy, 1383.

Doctors who have performed these experiments are not unfeeling men, 1493; does not know a kinder man than Dr. Sanderson, 1475–7.

Ocular demonstration
often necessary.

Experiments for Demonstration.—Considers that scientific education is necessarily based to a large extent on the evidence of the senses, and the question often arises whether a class is to be instructed by one experiment performed by the professor, or whether each individual should experiment for himself, 1454; such phœnomena as the action of the heart and the vermicular motion of the intestines for instance, can be demonstrated by painless experiments in a way which no other method, either artificial representation or description, can equal, 1464, 1455–8; and sees no reason why experiments before classes should exert a bad influence, 1497; considers moreover that the study of physiology necessarily involves a limited sacrifice of animal life, which is, however, as nothing in comparison with the common uses to which animals are put, 1458; on the other hand, would not be disposed to consider such an eminent man as Dr. Taylor wrong in saying that experiments on live animals are not necessary in toxicological education, 1463.

Limited
sacrifice of
animals
often necessary.

Dr. Sanderson's Handbook.—Thinks Dr. Sanderson's Handbook is an encyclopædia of reference for experts, not an educational handbook for the ordinary student, 1500; it is mostly used in England for anatomical preparations, the painful experiments are undertaken by very few, and then only in part by each experimenter, 1481.

Regulation of Vivisection.—Thinks public opinion has taken an exaggerated view of the matter, and that special legislative influence is unnecessary, 1382, 1384; if there be an evil, the remedy lies in the province of

conscience, not of legislation; has a strong objection to the latter, and cannot conceive a law for the protection of frogs, 1501.

Objects to
special legislation.

Objects to the special case of pain caused by the physiologist being separated from the vivisections and castration of animals by farmers, &c., for which the resulting human advantage is the only justification, 1502; refers to the preamble of Dr. Lyon Playfair's Bill, and thinks it altogether monstrous that society which slaughters animals for its food, emasculates them for its advantage, hunts them, wounds them, and kills them for its pleasure, should treat physiologists, who make these experiments for great human interests, as a dangerous class, to be licensed and regulated like publicans and prostitutes, 1491–2; is aware that several most eminent men had some part in the preparation of Dr. Lyon Playfair's Bill, and that the preamble might be easily modified, 1504–8; but thinks the eminent men from whom the Bill emanated have not quite considered what its operation would be, 1508. Points out that section five of clause three would enable physiologists to be held up individually to popular odium, 1509–10.

Dr. Lyon
Playfair's
Bill.

Believes that limiting experiments to certain places and certain persons would either drive investigators abroad or be a dead letter, 1488–9; it might be proper if any great abuse, which he does not believe, existed, 1490.

Is of opinion that an experimenter not having a reasonable prospect of attaining a result beneficial to mankind, or who was incompetent or negligent in the prevention of pain, would be liable under the Cruelty to Animals Act (1849), for "cruelly torturing" an animal, if it were a domestic one, 1385–6. If the Act does not include such cases, it might be made to do so, 1386; and its terms might be enlarged to include all animals, domestic and otherwise. Frogs and mice, the frequent subjects of experiment, are not, as it now stands, protected by it. Alterations of this nature would introduce a certain elasticity into the law, and it would then devolve on magistrates to decide as to the degree of suffering caused, 1388–95, 1503.

Suggests
enlargement
of "Cruelty
to Animals"
Act.

Mr. JOHN COLAM.

Secretary to the Royal Society for the Prevention of Cruelty to Animals, 1515–6.

Experiments in England generally.—Believes English scientific men generally try to prevent pain as far as possible, much more so than foreigners; does not know a single case of wanton cruelty, 1543–8. Believes that although anæsthetics are sometimes neglected when they might be used, 1530–2, their use is general in England, 1543; and as Dr. Brunton pointed out to witness animals would be narcotised to facilitate the operation if for no other purpose, 1568, *page* 81. In experiments producing protracted pain in which the use of anæsthetics has not been attempted, it would probably be found that their employment would have defeated the object of the experiment, 1540–2.

Anæsthetics
sometimes
wrongly
neglected.

Desires to point out that the society does not advocate the total abolition of experiments, 1567; but believes that many experiments are of such a nature that their object does not justify them, 1549; considers, for instance, the experiments of the Medical and Chirurgical Society on dogs, who were kept under water during various periods of time, then resuscitated, and half drowned again, was very cruel and, as in the end it proved, useless, 1533; and points out that in some of Brown-Séquard's experiments animals were kept suffering for weeks, 1544.

The Society
desires regulation, not
abolition.

Cruel experiments.

Admits that it is difficult to say when a truth has been established, 1551; but objects entirely to experiments for demonstration, 1551; they should be forbidden; incompetent persons should be prohibited from attempting experiments; and anæsthesia should be insisted on, 1569.

Experiments for
teaching
purposes
should be
forbidden.

Puts in statement quoting, with references, reports of various classes of experiments, showing that some were painful, others both lingering and painful, others performed to teach vivisection, and in one instance were undertaken by students alone, 1533–9; foreign experiments are omitted, except when recommended in English publications, 1569 (*Appendix IV.*).

Statement
of objectionable experiments.

Proceedings of the Society with regard to Vivisection.—Reads a letter from the society referring to witness as the society's representative, and stating what course the society has taken with regard to vivisection, what means it has adopted to get evidence, and what information it proposes to lay before the Commission, 1568.

Operations for acquiring surgical dexterity in France.

The society opposed several years ago with much success the practice of operations for the sake of acquiring surgical dexterity, which were then in vogue in the veterinary schools at Alfort and Lyons, 1568, *page* 79.

Vivisection thirteen years ago.

Thirteen years ago the society sent letters to the medical schools of England asking for information with regard to vivisection which was willingly given, and although the operations were very few in number, it was deemed advisable to offer prizes for the best essays on certain points; puts in the essays referred to, 1568, *page* 79.

Prosecution at Norwich.

Results of application to the medical schools for information.

Puts in a report of their proceedings against Dr. Magnan and others for cruelty to dogs at the Norwich meeting of the British Medical Association, 1568, *page* 80. Puts in a copy of the memorial presented to the society asking it to try to repress vivisection, 1568, *page* 80. On receipt of which a committee, the names of the members of which shall be given, 1701–2, was appointed to consider the matter, and after long and frequent meetings reported that they had the greatest difficulty in obtaining information on the subject; that they had addressed a circular to the hospitals and schools of the metropolis, asking the managers to supply particulars and to permit the secretary to be present when experiments were being performed; that from 14 institutions no replies had been received, in 30 no experiments were performed, from four evasive replies were received, and in five admission was refused, 1568, *page* 80.

The memorialists were also asked to supply particulars with regard to the vivisection of which they complained, but no specific information was obtained, 1569; believes this committee were of opinion that vivisection had not improved the treatment of disease, 1608–700.

Frequency, nature, and abuses of experiments in England.

Extent of Practice of Experiment.—Considers that the medical journals and works of physiologists prove that vivisection is frequent in this country; that anæsthetics are frequently not employed; that the object of these experiments is sometimes discovery, sometimes demonstration; that the same experiment is repeated many times; that painful experiments, where the suffering lasts days or even weeks, are not infrequent, and that students are being instructed by means of handbooks, &c. in the art, 1569; and the results of his own personal observation confirm this opinion, 1518–9; and make him believe that continental views are making rapid progress in this country with regard to vivisection, 1569; Dr. Hoggan referred to in support of this statement, *ib.*

Anæsthetics are used in demonstration.

From the evidence with regard to schools, it appears that there are few operations before classes, but many exhibitions of animals for demonstration after operation under anæsthetics, and some private vivisection by students; puts in a paper on the latter subject, 1569.

Guy's Hospital.

Witness gives detailed account of his visit to Guy's Hospital, in the course of which he ascertained that students are never permitted to perform experiments or to see them, except on insensible animals, 1568, *page* 80.

Learned from Dr. Pavy various details connected with experiments; saw some of the animals to be experimented on, and was informed that about 18 animals a term were used for purposes of demonstration under anæsthetics, 1568, *page* 81; and that Dr. Pavy's experiments were always conducted under anæsthetics and the animals usually killed before consciousness returned; even when consciousness is allowed to return pain is often nearly if not quite absent; instances a dog in which biliary fistula of the stomach was produced, and refers to absence of pain after amputation in the human subject, 1568, *page* 81; ascertained from Dr. Pye Smith that his vivisectional experiments were always conducted under anæsthesia, and that experiments with new drugs were being then tried on animals, 1658, *page* 81.

St. Bartholomew's.

At St. Bartholomew's saw Dr. Brunton perform several experiments in his private laboratory on cats and frogs wholly or almost entirely insensible, 1568, *page* 81; the object of the experiments was to ascertain the nature of the action of certain poisons, and to seek an antidote; the animals were destroyed, 1569.

Has inquired at every school in London, and has not found one in which the operation is performed before the students, the animal is operated on in the laboratory and then brought out for exhibition, 1550.

Method of obtaining animals.

The animals are obtained in a secret and confidential way, 1569, which was discovered by watching and inquiry from the vendors; gives some particulars, 1637–43.

Experiments by students.

Reads a letter from Mr. Mills, formerly student at Edinburgh and sometime lecturer at the New Veterinary College there, and now attached to the Royal Artillery, stating that he had himself witnessed vivisections by students at Edinburgh, made from idle curiosity and from reckless love of experimentation; details a most cruel operation on a cat to show the action of the heart; the victims in these experiments were dogs or more often cats caught by a poisoned bait or a "cat hunt;" in a few instances the animals were narcotised; these experiments were not known of by the professors, 1622, 1682–8; no case of experimentation by students has been found in London, 1683.

Section of a live lobster by a lady physiologist

A live lobster was cut up by a lady physiologist in the presence of a class of girls, and part of it afterwards crawled on the table; it was subsequently explained that the lobster, which had been brought in a bag with a dead rabbit, was believed to have been dead, 1569, 1614–21; at Billingsgate lobsters are killed instantaneously by being put into boiling water, 1644–6.

Popular lecture by Dr. Ferrier.

Alleged levity of description.

Professor Ferrier, in a popular lecture about six months since at the London Institution, described in humourous terms, amid great amusement, the involuntary contortions produced after the removal of a portion of the brain by irritation of certain parts of the cerebral hemispheres in the monkey, 1569, 1573–92, 1595; admits that the experiment which was not shown to the audience must have been commenced under chloroform, and that the subsequent portion, if the brain were in part removed, would also be painless; and does not refer to the incident as showing any cruelty on the part of Dr. Ferrier, but as showing the levity with which these experiments are regarded, 1596–613; believes there were no reporters present, but an account of a similar lecture was published in the north of England, 1593–4, 1609–10.

The Handbook for the Physiological Laboratory.

Regards Dr. Sanderson's handbook as an attempt to train students to the practice of experiments. It says in the preface it is for beginners, and describes in detail the appliances necessary, 1623–6; thinks that teachers of physiology advocate experiments being shown to students, and often their being taught to perform them; gives examples, 1627–31.

Puts in draf of Society's bill.

Proposes that *all* painful experiments should be forbidden

Regulation of Experimentation.—The society has embodied its wishes in a bill (*Appendix* III., § 5,) 1520–2, in which some of the provisions of Lord Henniker's and of Dr. Playfair's bills have been adopted, 1557–8; the society would like the bill passed unaltered; failing that, in as nearly as possible its present form, 1695; it differs from Dr. Playfair's bill mainly, in providing that *no* painful experiments should be allowed, 1559, 1561–2, 1565, even for purposes of investigation, 1527; the section of a polyp, if that causes pain, would be forbidden by the bill, 1659–60; it also provides if an experiment be performed under anæsthesia that the animal shall be destroyed before recovering consciousness, 1523–6; and forbids those which entail pain during recovery, even if performed under anæsthesia; the pain, for instance, after the ligature of an artery is often severe, 1528–9.

Such experiments as Bell's woul be forbidden.

The society as a whole disapproves of experiments for investigation when performed partially under anæsthesia; admits that of the individual members of the society some would go farther, some not so far, 1552–6. Hopes that such experiments as those on dogs with regard to suspended animation will be forbidden, 1655.

Also those which resulted in Palmer's conviction.

And those being made to discover an antidote to snake poison.

Admits that Bell's great experiment on the roots of the nerves would be stopped by the proposed bill, but points out that only one experiment was performed, and that only, Sir Charles Bell said, to convince people who did not use inductive reasoning, 1647–8; admits that any similar experiment would be forbidden by the bill, although it might be of equal importance, 1649–54; such experiments as those with regard to the action of strychnine, which had so much to do with the condemnation of Palmer, would be forbidden by the bill in its present form, 1692–4; as also those now being carried on by the Government of India, for endeavouring to find an antidote for snake bite by inoculating animals with the poison; quotes Sir W. Fergusson's opinion that these experiments are useless, 1689–91; will not affirm that an antidote can be discovered in any other way, but it might, 1697; believes the committee had the question of snake poison before them, 1696.

Also theoretically those on sheep-pox and choleraic discharges.

Admits that experiments in which sheep have been inoculated with the small-pox would, assuming them to be painful, be forbidden by the bill, 1656–8; and that the experiments with regard to choleraic discharges, which had such beneficial results, would technically come under the terms of the bill if they caused much pain to animals, but the society would not prosecute any more than in the case of a horse over-ridden to save life, 1678–81; points out that the Cruelty to Animals Act is liable to the same theoretical objection, under it the sheep-pox experiments might be argued to be "torturing" animals, but public opinion does not sanction such a view, 1663.

ut "cruelty" must be easonably nterpreted

Does not think demonstrating the circulation of the blood by the exhibition of the web of a frog's foot would come under the head of painful experiments, 1661–2; the society does not wish the wording of the bill to be qualified as regards experiments giving pain, 1676; but that a reasonable interpretation should be placed on the word "cruelty" as in other instances, 1671–2.

y the court, and experts alled if needed.

Does not wish to imply that the society should be empowered to act as judges on physiological investigators, 1665–7; but believes that the society could judge whether the results were useful without a knowledge of technicalities, 1669–70; or if not, whether a case would be a fit one for commencing a prosecution, and the court would determine whether cruelty existed or not, 1672–4; experts as in the Norwich case might be called on either or both sides, 1675.

The society would wish in any bill that the existence of what should reasonably be included under "cruelty" should be left to the court, 1677.

Record of all experiments

Licences.

The bill also provides for the record of all experiments, so that the value of the results might be known, and that by the publication of the results repetition might be made unnecessary, 1560, 1664–6, 1668. Like Lord Henniker's bill, it provides for licensing certain places, and extends this course to persons also, 1563–4, 1566.

Search warrants.

Has never known directly or indirectly an instance of cruelty to animals by medical men in their own houses, 1632–3; but believes that when licences have to be obtained, there will be a temptation to experiment without them; provision was therefore made for the issue of search warrants; has known many cases of strong suspicion in which they would have been asked for if the power of granting them had existed, 1634–6; in one instance at least there was reason to believe the law was being infringed, 1559–60.

ARTHUR DE NOÉ WALKER, M.D.

Was originally a military surgeon, served in the Crimea, and is now practising as a physician in London, 1703–6.

Was formerly a student in two or three physiological laboratories on the continent, and has kept himself acquainted with what has been published both at home and abroad, 1707–8; devoted especial attention to the subject in the years 1856–8, and again in 1872, 1709.

Has been in communication with the Secretary of the Society for the Prevention of Cruelty to Animals, but had compiled notes, in the hope of appearing before the Commission, beforehand, 1720.

Extent of Practice of Vivisection.—The practice of vivisection is a new phase of research, and is extending, 1717.

Draws a very marked line between pure physiologists and practical medical men, 1775–6; the former inquire into the functions of different organs irrespective of results, 1777; while many eminent medical men have never performed a single experiment, 1778.

Classifies experiments.

Divides vivisections into classes according to their objects, viz., those with physiological objects, those for the sake of ascertaining if a proposed operation is likely to be successful, those for acquiring manual skill in surgery, those for studying the effects of injuries, 1721, *page* 89, considers experiments under this head are very numerous and often aimless and ill-conducted, 1726, and has therefore made them the subject of a separate paper, and lastly, those relating to electro-physiology, to the artificial generation of morbid states, to the experiments testing the effects of drugs and other substances, and to these last experiments he wishes to specially refer, 1726.

Excessive amount of experiment.

Considers there is a great deal of wanton and unnecessary suffering in foreign laboratories, 1710, 1712; judging from the voluminous accounts of vivisections in the "Gazette Medicale de Paris," 1712–6; from the English medical press it would appear that some such experiments are performed in this country, 1711, and also that the number of experiments is very excessive, 1810; believes that a very large number of experiments involving pain are performed by incompetent persons, 1800.

Refers to the "liberal" supply of animals for experiment provided at the West Riding Lunatic Asylum, as evidence that the practice is extending, 4888, *page* .

Has made one or two attempts to get into laboratories in England, but found it impracticable, 4904, being known as having written against the practices going on

in laboratories, 4906; would rather not mention the names of the laboratories, 4905–9; gives another instance of refusal to allow admission to a laboratory, 4904.

Alleged value of Physiological Discoveries.—Physiologists base their justification of vivisection on the therapeutic value of their discoveries; without going so far as to say that physiology is of no use to the physician, witness maintains that it has never led to the discovery of a single remedy or to improved treatment, 1721, *page* 89. Science has made as many blunders as empiricism, 1770.

Sir William Gull.

Professor Rivière.

Quotes Sir W. Gull's opinion, that "the clinical "physician knows that the phenomena of disease are "not explained by the phenomena of healthy texture, "nor by the action of healthy organs," 1749; refers to Professor Rivière's assertion "that the discovery of the "circulation of the blood had not advanced medicine a "single step," 1721, *page* 90; and would agree with him if he had said "therapeutics" instead of "medicine," does not think he meant his observation to include surgery, 1789–90.

Physiology is of little practical value except to localise disease.

Contends that physiologists mislead themselves and their pupils, some even saying that "physiology is the "foundation stone of pathology," yet the physiologist knows nothing of the nature of marsh miasma, for instance, or its action on the frame, while the physician knows that quinine will cure the disease, 1721, *pages* 89, 90.

Maintains that a knowledge of the functions of an organ in health is no guide of itself to the treatment necessary in disease, 1721, *page* 89, 1738; the knowledge of the functions of the liver or kidneys is no use in diagnosing the diseases of those organs, 1739–42, 1758; refers to scurvy, diabetes, gout, intermittent fever, and other diseases, and points out that in each case the remedies used were discovered by the physician, and that none have been suggested by the physiologist, 1721, *page* 89.

Ringworm.

In ringworm many efficient remedies were known before the disease was discovered to be produced by a parasite; admits that this knowledge however was a great advantage, it placed a definite object before the pathologist,—kill the parasite and the disease is cured, 1762–3, 1769.

The sounds of the heart.

Was not aware that the exact cause of the second sounds of the heart had been ascertained by physiological research, but maintains that although anatomy and physiology may help to determine the seat of the disease, they are no further help, 1749; and points out that physicians were the discoverers of the action of digitalis, aconite, &c. on the heart, and that physiologists are unable to explain the causes of such action, or to suggest other substances which would act analogously, 1721, *page* 89.

Ligature of arteries and transfusion of blood.

Has not any personal experience with regard to vivisection for surgical objects, but admits the value of the knowledge of the possibility of the deligation of arteries and of the transfusion of blood; considers the latter however an invention rather than a discovery, and believes that these and all similar discoveries were made by physicians and surgeons, not by physiologists, 1721, *page* 90; thinks the discovery that nitrite of amyl was a remedy for *angina pectoris* was a lucky guess, any agent having an elective affinity for a given organ is generally tried for most diseases of it, 1781–2.

Angina pectoris.

Experiments for acquiring surgical dexterity.

Believes experiment for the sake of acquiring manual dexterity is never practised in England, 1793–5; Gooch excised the rib of a dog to see if it might be possible in the human subject, 1793–4; when a student abroad, a surgeon trephined the skulls of six goats with the object of discovering its effect by post-mortem examination; considers this purposeless, 1721–6, 1791–2.

Majendie's experiments in feeding animals exclusively on gelatine or on albumen were dietetic rather than therapeutic experiments; witness was present at the latter, 1783–4.

Small-pox.

Sheep-pox.

A *full knowledge* of the processes of small-pox and other diseases would be desirable if possible, but even this would not point out the remedy, 1761, 1764, 1767; physiology discovered the existence of the *acarus scabies*, but pathology that sulphur would destroy it, 1761; is aware that sheep-pox is the work of a small organism; thinks this knowledge important as pointing to the possibility of prevention rather than as suggesting a cure, 1765–6; admits that the knowledge of the processes of inflammation is due to experiment, but such knowledge has not led to the discovery of any remedy, 1760.

Localisation of disease.

Considers that etiology, pathology, physiology, chemistry, and a knowledge of the action of remedies all are of use in the treatment of disease, and that the part of physiology is to localise the disease, 4911–2; especially in nervous affections, 1739; it usually, but not always, effects this, 1759; but is of no further use, 1721, *page* 90; 1750-3, 1757.

Believes the eminent medical man who stated that he was generally greatly indebted to physiologists in his practice was wrong if he meant more than that physiology enabled him to localise a disease, 1779-81.

Pathological experiments are useful.

Admits that the practice of experiment by the induction of disease has been too recently introduced to bear much immediate fruit, 1785–6; and concurs in thinking that any further advance in pathology must be made by means of the microscope and pathological experiment jointly, 1787–8.

Admits that the functions of the various parts of the nervous system have been ascertained by experiment, 1754–6.

The abnormal conditions of these experiments interfere with the results.

Points out that experiments on live animals are constantly made under conditions which could not arise naturally, and that the results are often therefore useless, 4888, *pages* 243–4; has witnessed various experiments in which an inflammatory state has been artificially induced; the experiments were most painful and gave no rest day or night to the victims; maintains that any knowledge thus obtained is generally rendered valueless by the fact of its having been induced in a previously *healthy* tissue, and not being the outcome of a morbid state, 1727–8; instances many cruel methods of introducing poisons into the system of animals, and points out that these methods never occur naturally, and that an unnatural condition is introduced into the experiments by them, 4888.

Unnecessary prolonged suffering and useless cruelty.

Biliary fistula in cats.

Animals are kept alive much longer than they ought; instance the case of frogs who are kept nailed down until nature wears out under electric experiments, 1729–30. Has himself seen frogs kept for months in closed jars until ulcers formed around the mouth; even then the man in charge was not blamed, 1730–1; instances the injection of boiling water into the stomach and sand into the veins of dogs, as examples of wanton cruelty; will not say that the operators had no object in view, but certainly no demonstrative purpose was served thereby, 1802–8, 4888, *page* 244; "would have suspended from rank and pay" the physician who vivisected 16 cats with nearly the same results; considers such a man ought not to be licensed as an experimenter, 1810.

Puts in a statement of experiments which he desires to bring before the Commission, 4887–8. The descriptions are taken from the writings of Claude Bernard, Schiff, and others, from the "Medical Times and Gazette," the "Gazetta d'Italia," &c., 4888, *pages* 244–5; in these descriptions no reference is made to anæsthetics; in many instances they would be impracticable; in others, if used during the operation, the prolonged suffering afterwards remains, 4889–90.

Details of uselessly cruel experiments.

Refers to several of the experiments described; characterises as unnecessary and cruel experiments, starving rabbits until they ate dead frogs, 4888, *page* 244; 4898–9; in the experiment in which portion of a living frog is placed in the stomach of a live dog to show that the gastric juice will dissolve living substances; points out that dogs do not swallow live frogs; that the frog might have been removed as soon as the action was evident; that it might have been pithed; and that its repetition for demonstration was cruel and needless, 4888, *page* 244; admits that birds swallow frogs alive, but thinks this goes to prove the experiment unnecessary, 4902–3.

Non-natural food.

Starvation.

Starvation and wounding.

Injection of boiling water.

Cerebral fungus.

"Frightful struggles" of a cat.

Considers forcing Liebig's extract of meat into the stomachs of rabbits was an experiment against nature, 4888, *page* 245; but is aware that in Norway cows are fed in winter on a mixture of stockfish and cow dung, and has also known them fed for months on lemons, 4900–1; dogs and rabbits having the fifth pair of cranial nerves severed, and being thus unable to swallow are allowed every season to die of hunger instead of being killed, 4888, *page* 245; doves and pigeons starved until they were too weak to stand, and then subjected to amputation of one of the extremities which produced immediate death, showing, what every old dame in Europe knew, the combined effect of suffering, starvation, and wounds, 4888, *page* 245; considers placing, first, a frog with the medulla oblongata divided, and then a sound frog, in cold water and raising the temperature until they are killed, horrible; also the injection of boiling water into the stomach of a dog, 4888, *page* 244; puts in sketch of a frog nailed to a board and deprived of food, in order to test from time to time the effects of nervous exhaustion, 4888, *page* 245; refers to an experiment in which an animal was kept alive with the greater part of one of its cerebral hemispheres exposed for five days, during which it gave rise to a fungus; points out that under a proper system of control the necessity of thus keeping the animal alive would have been called in question, and that various other physiological problems might have been solved at the same time, and the necessity of further experiments avoided, 4888, *page* 243; refers to "one of the frightful struggles so common in physiological laboratories," in which meat, steeped in decoction of colocynth, was thrust down a cat's throat, only to be rejected, whilst another cat, in which the glosso-pharyngeal nerves had been excised, ate some, 4888, *pages* 244–5; 4891–7.

Anæsthetics.—Believes it to be literally true that "anæsthetics are used," but it is nevertheless often a pure delusion to believe that the animals are kept in a state of insensibility, 1810.

Curari not an anæsthetic.

Considers curari is not an anæsthetic; a dog whose respiratory organs are paralysed by it will try to wag his tail, and will follow you round the room with his eyes, 1731–5; quotes Claude Bernard, that animals under its influence "feel pain but cannot manifest it," 1735.

Vivisection for teaching purposes should be forbidden,

Admits the value of instruction conveyed by ocular demonstrations, 1731; and that anatomical demonstration is a necessity, but vivisection for physiological demonstration should be forbidden, the suffering entailed being so great and a verbal description being sufficient, 1701; most medical men have learned physiology, as anybody might, solely from description, 1809.

except under anæsthetics.

Vivisectors are not exempt from the law of habit; they are hardened both morally and physically; instances a case of the different way in which suffering is regarded by those experienced and those inexperienced in vivisection, 4908–9; would certainly not allow his son to see demonstrative experiments, except under anæsthetics; sees no objection to them then, provided insensibility be maintained to the end, 4910.

Legislation is necessary

Regulation of Vivisection.—Considers there is a decided necessity for State intervention which would not, he believes, interfere with research, but rather the reverse, 1718. Personally would like to see vivisection forbidden; it seems a necessary evil, however, and therefore witness advocates its legal restriction, 1737.

Licences.

Is of opinion that no person should be allowed to experiment unless licensed, except analysts in cases of poisoning, 1729; and that the number of animals allowed yearly to each experimenter should be limited; believes this would prevent experiments by unlicensed assistants, 1729; at present many cases have occurred in which 10 to 30 animals have been experimented upon with the same result, 1729.

All experiments on living animals not having a definite object should be forbidden; the advantage resulting from the prohibition of useless experiments, such as the injection of boiling water into the stomach or sand into the veins of dogs, 1801, would counterbalance the possible prevention of some useful ones, 1797–9.

Returns showing past and proposed experiments should be required.

A return should be required each year of the experiments intended to be performed, and another showing the results of those that had been performed; the first would prevent unnecessary and the second careless experimentation, 1729; is sure that scientific research could be conducted with greater economy of pain than it is, 1735–6.

Uses of these returns.

Believes that the list of proposed experiments would enable a competent inspector to say whether a given experiment had been performed before; if so, repetition should not be allowed unless there was reason to suppose it had been defective, 1796; the inspector in allowing the repetition of an experiment would be able to refer the experimenter to the previous experiment, and the cause of failure might thus be avoided, 1800; the second return should state whether anæsthetics were used, and how long the animal was kept alive, 1729, as proper supervision is required, not only as regards animals to be, but on those which have been, experimented on, 4888, *page* 243.

Surgical experiments.

Does not think any control is requisite with regard to vivisection for surgical experiment, except to provide that it should be done by clinical surgeons only; surgery is so perfect that very few experiments can be needed, 1721.

Suggests a board of control.

Inclines to the institution of a board of control for scientific experimentation on animals, comprising physiologists, physicians, surgeons, pathologists, and possibly a chemist, 1771–4.

LAWSON CAPE, M.D.

Formerly in practice in London, 1811–2; and for 10 years lecturer at St. Thomas's Hospital, 1820.

Has been out of practice 8 or 10 years, and has not attended to the subject since, 1833–4; and has no practical knowledge of the schools since the year 1847, 1837–9. Is not a member of the Society for the Abolition of Vivisection, but to a certain extent agrees with them, 1813–6; although not recommending the total abolition of experiments on live animals, 1832, deprecates their extension, 1819. Believes that the present surgeons and physicians are efficient practitioners, and have never had anything to do with vivisection, 1817–8; and does not see any educational benefit likely to result from its introduction in the schools, 1821, 1836.

Experiment for demonstration is not necessary.

Never saw vivisection in Great Britain; was more than two years in Paris; and then it was not recognized although done secretly, 1820, 1835.

Approves of the system of licence by the Secretary of State if accompanied by proper regulations, 1826–7, 1831. Considers that vivisection should not be allowed on the dog and other highly organised creatures, 1822–5, 1828; but does not think worms for fishing, and the lower animals feel much pain, 1829.

GEORGE MACILWAIN, F.R.C.S.

In practice in London until about four years since, 1840–1.

In early life was acquainted with Mr. Abernethy, 1845–6; and did a little vivisection himself, 1853; and having studied the writings of Hunter and Lord Bacon, witness became much impressed with the fallacies commonly accepted as facts by the medical world, 1845–6. On several occasions has offered to advocate his views in public, but has not had an opportunity afforded him, 1845–6, 1854, 1858. Puts in the first volume of a book printed by witness advocating the inductive method in medical science, 1845–46, and pointing out the uselessness of vivisection, 1847–9; this work has been re-published in America, 1859. Has communicated with the Society for the Prevention of Cruelty to Animals with regard to vivisection, 1842–4.

Advocates reasoning by induction.

Observations on the valves of the veins, not vivisection, led to Harvey's great discovery.

Denies that the circulation of the blood was discovered by vivisection. Fabricius discovered the valves in the vein, Harvey saw that they only allowed the blood to flow in one direction, and hence discovered that it circulated, 1845–6; besides, if in the dead body you inject a fluid into the arteries, it returns by the veins, 1845–6.

Aneurism.

Refers to Hunter's experiments with regard to suppuration and aneurism, describes the nature of the latter; the old treatment was to tie the artery above and below the aneurism, but this operation was often fatal, because, as Hunter said, the artery when tied was in a diseased condition. Points out that Hunter's experiments on animals to prove this were fallacious, as animals cannot have aneurism induced in them, 1845–6.

Fallacies in arguments, based on experiments on animals.

Refers to Mr. Travers' surgical experiments on the intestines of dogs, points out the error of the conclusions he deduces therefrom, and the want of analogy between the operation on the dog, and that for strangulated hernia in the human subject to which Mr. Travers' deductions were applied; witness believes that hundreds of lives have been saved by his having succeeding in getting the treatment recommended by that experimenter given up 1850–1. Quotes Mr. Stanley of St. Bartholomew's in support of this, 1852.

Loss of human lives therefrom.

Vivisection a fallacious method of investigation.

Considers it is demonstrable that vivisection has been not only useless but misleading, 1859; and that experiments on animals have led to serious practical errors, 1850, and have not conduced to the cure of human infirmities, 1847; prefers, however, to rest his condemnation of vivisection solely on the ground that it is demonstrably a fallacious method of investigation, 1855–8.

Rev. SAMUEL HAUGHTON, D.C.L., M.D., F.R.S.

Fellow of Trinity College, of the College of Physicians, and of the College of Surgeons of Ireland, Registrar of the School of Physic, and Honorary Secretary of the Royal Zoological Society of Ireland, 1860–6.

University of Dublin.

Puts in the regulations of the University of Dublin prohibiting vivisection, 1867, *page* 99, which may be taken

as expressing the views of the College of Physicians of Dublin, also, as both bodies are concerned in the management of the School of Physic, 1869. Describes the government, &c., of the School of Physic, 1868. Points out that the University of Dublin not only forbids vivisection itself, but will not recognise the certificates of schools in which it is permitted to the students or used for demonstration, 1867, *page* 99. In these regulations "vivisection" is understood to include all experiments on living animals, excluding the exhibition of animals freshly killed, by means of which, as artificial respiration can be kept up, very many experiments, such as Weber's on the pneumo-gastric nerve of the heart can be performed, 1917–8; these regulations were made when the physiology class was started a year and a half ago, 1898. Experiments on pithed frogs are permitted, but those on animals under anæsthesia are forbidden on account of the difficulty of securing that complete anæsthesia is maintained, 1919–23.

Certificates from schools in which vivisection is practised for demonstration not received.

No experiments for demonstration allowed except on pithed frogs.

Professor Purser conducts the classes in physiology and histology without experiments on live animals, and finds no practical difficulty on that ground, 1870–1, 1927–33, 1971; although as a matter of feeling he would doubtless prefer to be unfettered, 1903–7; the professors of the five extra-academical schools also agree that vivisection is unnecessary in lecturing, 1900–2.

Results arrived at by Experiment.—Considers that the value of these experiments is often exaggerated; instances the extensive series of experiments by Dr. Hughes Bennett with regard to the action of mercury on dogs' livers, which were of great value as regards sick dogs, but of none as regards sick men, 1875; and physicians therefore rightly adhere to the old practice which experience has justified, 1934–6.

Treatment proper for dogs not therefore good for men.

Biliary fistula.

Voted for the grant for the experiments on biliary fistula, but was disappointed at the smallness of the result, 1954; admits, however, that a negative result is often important, 1955.

As an instance that you cannot argue by analogy from one animal to another, refers to some experiments of his own, with regard to the action of strychnine and nicotine, by which he ascertained that a frog might be speedily killed by a bath containing either poison, but that in a bath containing both poisons in certain proportions a frog would live for weeks. On trying the experiment on dogs, it was found not to have the same effect. The result on frogs having been published. Nicotine was tried as an antidote for strychnia in America and proved, as it has since done in five or six cases, successful, 1875, 1911–2.

A mixture of poisons innocuous to frogs, poisonous to dogs, and an antidote for man.

Results often vitiated by the pain and the anæsthetic.

Points out that in these experiments animals are disturbed by pain, and also by the anæsthetic. The products of the blood and the secretions differ greatly from those of animals in health, 1894–7.

Limits of Experimentation.—The true use of vivisection and pathological experiment is original research, 1867, *page* 99; but so much nonsense is talked with regard to it that if nine tenths of it were stopped no harm would be done, 1960–1.

It should be limited to competent persons in pursuit of definite objects, and should be under regulations, 1946, 1964–6. It would not do to trust the enthusiastic dissector to keep up anæsthesia as long as he ought unless it facilitated the operation, which it does not invariably, 1892–5; and painful experiments should be forbidden if other means were possible, 1967.

Justifiable for definite objects only.

Considers experiments for the advancement of science are justifiable, but only when undertaken with a definite object, 1952–3; and thinks that if an experiment opens up further questions they in turn should be solved under proper supervision, 1956.

Considers that a man may qualify himself to conduct a physiological laboratory without experiment on live animals, just as surgery is learned without experiment on the living body, 1944–5.

Thinks the idea of shutting up the Zoological Gardens because confinement may produce disease in the animals absurd, 1937–8.

Experiments for demonstration.

Objects to experiments for purposes of instruction, whether under anæsthesia or not, 1872, 1876–7, 1963; both because, being performed under abnormal conditions, the results cannot always be depended on, and because they are unnecessary, 1897; is entirely opposed to Dr. Rutherford's extraordinary statement that vivisection is "essential" in teaching, 1943.

Evil effects on some characters.

Half a lifetime's experience has convinced him that the dissecting-room elevates some characters and degrades others, and he believes that accustoming students to the sight of animals under vivisection would produce in many cases young devils rather than men who would advance science, 1888.

The Norwich experiments.

The Norwich experiment was unnecessarily cruel, the absinthe should have been received through the stomach; besides, if the object was to ascertain its effects on men, one of the 2,000 men whose votes are purchasable might doubtless have been induced to get drunk on absinthe for a small consideration, 1874–75. Considers that the majority of the Medical Association would have forbidden such experiments, although the majority of those in the room were in its favour, 1874.

At Oxford the experiments proposed to be made by Professor Magnan were submitted to a committee beforehand, and some were prohibited, 1951.

Memorial to Society for Prevention of Cruelty to Animals.

Reads memorial signed by the most distinguished medical authorities in Dublin and by himself, addressed to the Society for the Prevention of Cruelty to Animals, setting forth the enormous extension of the practice of vivisection, even in England; its probable indefinite development; its liability to abuse; its deadening effect on public feeling, and suggesting that a sub-committee for the restriction of vivisection should be appointed; that prosecutions should be attempted under the existing law, and that if these failed a bill should be drawn up providing for licensing laboratories and persons, forbidding vivisections for demonstration, extending the time during which prosecutions may be commenced from one to three months, &c., 1867; reads a letter from the secretary of the Society for Prevention of Cruelty to Animals asking for assistance in collecting evidence with regard to the practice of vivisection, and reply from himself declining to assist in collecting possible evidence against scientific brethren, 1867.

Physiological Handbook.

Thinks Dr. Sanderson's Handbook valuable, but it unquestionably tends to encourage vivisection by students, and to extend the practice generally, 1939–42.

Often inefficiently administered.

Anæsthetics.—Has no difficulty in keeping an animal under chloroform himself, but from his knowledge of schools and students, believes any provision compelling their use would be laxly carried out, 1924–6; the practice is to use anæsthesia very imperfectly, and when the controlling eye is gone to drop it altogether, 1884.

Believes pithing a frog gives the means of making as many experiments as chloroform would, but some on the nerves cannot be performed with either, 1948–50; it is difficult to give anæsthetics to the lower animals without destroying them, 1947; has tried to produce anæsthesia in lions and tigers without effect, 1947.

Extension of the Cruelty to Animals Act useless.

Regulation of Vivisection.—Is aware that the present law protects certain animals only, 1885; but thinks an extension of it would be entirely insufficient; has been a frequent prosecutor under it, and finds the difficulty of getting evidence results in the acquittal of nine out of ten offenders; in fact, it tends to promote the suffering of animals, 1891; has not, however, come prepared to detail proposals for regulating research, 1962.

Reasons for restriction.

Considers that regulation is required, 1st, because young physiologists make clumsy and unnecessary repetition of foreign experiments; 2nd, because in many necessary experiments the method is often needlessly cruel, instance the Norwich experiments by M. Magnan; 3rd, because they are often undertaken without sufficient forethought and care; and 4th, and specially, because the importance of the results are over-estimated, 1874–5.

Thinks that vivisection for original research requires some such provision as that provided for anatomy by the Anatomy Act of 1834, 1873; experiments under anæsthesia should be equally under control with others, 1882–4.

Suggests similar law to the Anatomy Act.

The Anatomy Act of 1834 is an important guide in the whole question, 1878; and any controlling machinery set up should be similar to that at work with regard to anatomy, 1908–10, 1916, 1968; is inclined to think that if the inspector of anatomy were to act as inspector of physiological experiments in conjunction with a colleague appointed locally by the public it would be found to work well, 1886.

Necessity for the unprofessional world being represented.

Wishes to express his opinion very strongly that control should be partly under the direct influence of public opinion, so that the Legislature might know what was going on, 1969–70; the supervision should not be vested solely in a fellow physiologist, 1957–60.

Thinks experiments made by a medical practitioner to test the propriety of a certain course would be almost necessarily useless, and should be forbidden; if he wanted to enter upon a series of experiments he could obtain a licence, 1913–5; in the case of poison such cases must be purely hypothetical, 1972–4.

Lord Henniker's bill.

Objects to Lord Henniker's bill because it leaves out experiments for testing the effects of drugs; because it proposes to charge a fee for a licence, and thinks it goes too much into detail which should be left to the supervising body, 1880–1.

Licensed persons only should be allowed to experiment.

Dr. Playfair's bill.

Objects entirely to unlicensed assistants at these experiments being allowed; believes such assistants would actually perform the experiments, and that the practice would thus be extended among the students, 1881; thinks the clause in Dr. Playfair's bill allowing experiments to be conducted under the supervision of a licensed experimenter is intended to have the effect of enabling experiments to be handed over like the post-mortems at a hospital to the youngsters, 1887.

Licences.

Objects entirely to the clause in Dr. Playfair's bill empowering the presidents of the Royal Society and of the Colleges of Physicians and Surgeons to issue licences; there would be no control under such a system, 1881.

MR. ALFRED H. GARROD.

Prosector to the Zoological Society of London, 1975–6.

Did not go through a practical physiological course, 2020–1; but now performs experiments for his own instruction, but always under anæsthetics, 1976–8.

Experiments for demonstration not necessary.

Does not object to experiments for demonstration on pithed or decapitated animals, 2004; but has an instinctive aversion from demonstrative experiments before classes in special physiology, 1980, 1992; and objects to such experiments under anæsthetics because the animals can return to the normal state afterwards, 2005, and because an operator in public may often pay less attention to the feelings of the animal than is desirable, 1994; thinks, too, that the text-books for physiological students do away with the necessity for repeating experiments, 1995; and that enough can be taught without vivisection, 1986, 1993.

Believes the phænomena of the circulation of the blood are more easily learnt from description than from ocular demonstration, 2000–3.

Gives reasons.

Admits that in chemistry experiment is necessary for the student, 1996–7; but points out that the important subject of surgery is taught by text-books without experiment, 1998.

Admits that no one could understand the action of the living muscle from seeing the dead muscle only, 1999; but contends that although it is necessary to study its phænomena in original research it is not for demonstration, 1999.

Believes that the extra study required in getting up surgery or physiology from a text-book is quite balanced by the extra study necessary to enable a student to grasp the results of an experiment, 1998.

Surgical experiments.

Vivisectional surgery is objectionable, it used to be practised in France on a large scale, 1990; believes, however, that except in vivisectional demonstration abroad, and possibly at home, there is no abuse of the practice, 1989.

Anæsthetics.—Believes experiments under anæsthesia are painless, 1919; and is of opinion that by varying the anæsthesia according to the animal there is no difficulty in anæsthetising them; instances the giraffe, 2006–9; considers a disposition to move or make a noise a sign to repeat the dose of chloroform, 2023–6; and that perfect quiet during an important skin section is a sign of complete anæsthesia, 2022; has anæsthetised frogs with ether, the effects of which last a considerable time, but not with chloroform, 2028.

Animals at the Zoological Gardens.—More animals die of tubercle than of any other disease, the larger number from conditions which cannot be accounted for, 2010–6; the domestic animals live as long there as elsewhere, 2017; lions and tigers suffer from want of exercise, and live shorter lives, 2018–9.

Regulation of Vivisection.—Experiments for investigation by competent persons should be under no restriction whatever, 1980–1, 1991; experiments by incompetent persons would come under the Cruelty to Animals Act, 1982; admits, on the other hand, that the animals at the Zoological Gardens do not come under the Cruelty to Animals Act, 1983; but contends that two or three experiments will either make a man competent to perform such experiments or induce him to abandon the practice, 1984, 1987; there is no inherent attraction in vivisection, 1988.

FREDERICK WILLIAM PAVY, M.D., F.R.S.

Physician and Lecturer on Physiology at Guy's Hospital during the last 20 years, 2029, 2033.

Has always illustrated his lectures by experiments, 2108; but believes he was the first physiological lecturer in London who did so, 2033; a course of lectures lasts during the six months of the winter session, 2088.

Supply of animals.

For purposes of experiment uses dogs, rabbits, guinea-pigs, and frogs, 2089–90; which are bought in the ordinary way at Leadenhall Market, 2101–4; during the session about 20 dogs and 10 rabbits are used, 2096.

Performs another set of experiments for research, in which, unless there is a special reason, chloroform is always used, 2140–2; has always had in view ultimate benefit to the human race, 2127.

Humane feelings of students.

At the commencement of a course finds it necessary to tell the students that no experiments which will wound their feelings will be introduced, 2062–3.

Vivisection before a class without anæsthetics would not be tolerated in any large body of students at Guy's or elsewhere in this country, or by the profession generally, 2035–6.

All the experiments for demonstration are painless.

For lecture purposes *all* vivisection is performed under some anæsthetic, or in the case of frogs, on a pithed animal, 2033, 2141, 2091–2, 2097; when it is desirable not to weaken the action of the heart puff ball is used, 2097; in every case complete anæsthesia is maintained during the whole experiments, 2098–2100; a great number of the experiments, however, are chemical, 2118; instances an experiment to show the changing character of the blood by detecting a drug administered to the animal in the urine, 2093–5; has nothing to conceal, a member of the Society for the Prevention of Cruelty to Animals might be present at any lecture; everything was explained to the secretary of that society, 2105–7; has not found that these experiments have hardened the hearts of those who were formerly students in physiology, 2197–9.

Popular misapprehensions.

Extent of Practice of Experiments on Live Animals.—Much is done abroad which would not be tolerated here, 2060–1, and which might rightly lead in this country to regulative legislation, 2062; does not consider the practice has considerably increased in England of late, 2037; thinks the popular opinion to the contrary has arisen from "practical physiology" having been added to the list of subjects taught, the instruction given under this head really consisting, however, principally of microscopic work on the dead tissues, 2037; and from experiments, really entailing very small pain, being described in such a way as to appear horrible. Often the facts cannot be recognised from the description, 2106.

Does not believe experiments are conducted by incompetent or reckless persons, 2064–6; or by students in their rooms, 2066–7, 2086–7; or that purposeless experiments are made by scientific men, their time is too valuable, 2117–8; if experiments are being performed by incompetent persons or students they should be legislated against, 2066–8.

Does not know of any private laboratories, 2076–7.

In England the amount of suffering caused is very small.

The amount of suffering caused to animals in this country is almost insignificant, 2031; most experiments are under anæsthetics, and therefore painless, 2031–2; some experiments on the nerves are necessarily painful, but after the result is seen the animal can be at once put out of suffering, 2182–4; does not recollect any experiment on the liver which cannot be performed under anæsthesia, 2182; thinks that in resuscitating an animal poisoned by strychnia, by sustaining artificial respiration, the pain cannot be acute, the animal being under the action of the poison, 2148–9.

Anæsthetics.

Does not think any definite line can be drawn between experiments in which chloroform can be employed and those in which it cannot, 2177–9; has never found the slightest difficulty in keeping an animal under its influence even for three or four hours, 2205; apart from the question of feeling anæsthetics are of great help to the operator, 2099.

Not meant for ordinary students.

Physiological Handbook.—Considers Dr. Sanderson's Handbook meant for professors, not students, 2085; admits that the editors seem to have intended the book, as they themselves say, for beginners, but does not see how beginners could use it, 2150–1; the experiments are unfortunately described, but are not meant to be performed in the schools as would appear at first sight, 2081–2; many of them are not adapted for repetition, 2163–5, 2168–9; they are principally taken from continental sources, 2083, 2156; very likely most of the experiments have been tried by the editors, 2156; persons prosecuting physiology in the hope of benefiting mankind would be justified in undertaking experiments which would not be justifiable for ordinary medical students, 2167.

Frogs in hot water.

Argues that in the experiment of placing a frog in cold water and gradually raising the temperature the animal may not suffer much pain, 2159–62.

Recurrent sensibility.

Does not deny that the recurrent sensibility experiment is suggested in the handbook as one for the physiological lecturer, but it would not be performed at Guy's, 2152–4; it would not be tolerated, 2157, by any body of English students, 2193–6.

Does not think this book has tended to increase the practice of vivisection, 2084, 2155.

Physiology is the foundation of medical treatment,

Necessity for Experiment.—Physiology is at the foundation of the treatment on disease, 2128; the practice of medicine is based on it; before knowledge of diseased action is possible that of healthy action must be acquired, gives instance, 2122–4. Was much helped by experiments on animals in forming the views expressed in his books on dietetics, 2119–20. Has ascertained by experiments that the cause of death in poisoning by strychnine is the cessation of respiration, has performed the experiment demonstrating this under chloroform in lecturing, 2143–6.

and can be advanced and taught by experiment only.

Is convinced that physiology, like chemistry, can only be thoroughly taught by the help of experimental illustration, 2109–13; thinks the knowledge derived from seeing the action of a living heart and the peristaltic action of the intestines of inestimable value to a medical man, 2200–3. Cannot see how such knowledge can be otherwise obtained, 2204; the knowledge gained by hearing, reading, and seeing is likely to be more impressed on the mind than that resulting from hearing and reading only, 2125–6; besides seeing gives knowledge over and beyond that derivable from hearing and reading only, 2129; a medical student not only reads and hears descriptions of diseases but goes through the hospital and sees them, 2130–1. Physiologists untaught by experiments are like physicians without practical experience, 2132.

Considers that the difference between a limb in the living body and one in the dead body is not analogous to that existing between a dead organ and a living one in action; a man may have a thorough knowledge of the parts of a limb without any of the action of the living parts, hence the method of study which may suffice for surgery is not applicable to physiology, 2113–5. Denies that this argument proves that it would be desirable to experiment on human beings, to acquire thorough knowledge, on the ground that there is no essential difference as regards the great functions between man and the lower animals, in fact, setting aside the phenomena of consciousness the great physiological truths can be demonstrated on the dog, 2133–8; the higher functions would, however, be different, 2139.

Dr. Playfair's bill.

Regulation of Vivisection.—Sees no objection to experiments for demonstration being forbidden unless the operative part is performed under chloroform, 2191–2. Thinks the passing of Dr. Playfair's bill would pacify public feeling without interfering with legitimate vivisection, 2074–9; it would not alter a single practice in the London laboratories, nor he believes in those in the country, 2070–3; it would not restrict his own course, 2185.

PHILIP HENRY PYE-SMITH, B.A., M.D.

Assistant physician and lecturer at Guy's Hospital, 2038.

English experimenters are humane and Legislation is needless.

Practice of Vivisection.—Believes that in this country the practice of vivisection is pursued with due regard to humanity, and as far as possible under anæsthetics, 2048–9; has never known these experiments performed by incompetent persons, 2058; and thinks it is needless therefore to forbid such persons to perform them, 2059. Is not aware of the existence of any private laboratories, 2078.

Experiment is essential.

Considers that the study of physiology, in its full sense, is impossible without vivisection, 2040.

Sensational descriptions.

Agrees with Dr. Pavy in thinking that experiments are essential in physiology just as they are in chemistry; that there is no just force in urging that because practice on the living body is not necessary in learning surgery or anatomy therefore it is not as regards physiological education; that experiments are described in very horrible terms which really involve very little pain and that experiments by incompetent persons are unknown and improbable, 2108–21.

Anæsthetics are used in a large majority of cases, 2050–1, 2054; and complete anæsthesia is usually produced unless the anæsthetic be badly administered, 2052, 2054. Has himself never performed or seen a painful experiment on an animal without the use of anæsthetics, 2056. The number of necessarily painful experiments is necessarily small, 2057; and in them the most painful part is performed under anæsthetics, 2055.

The effects of drugs or of operations can only be judged of after recovering from anæsthesia, 2053.

Physiological Handbooks.

Agrees with Dr. Pavy in his opinion of Dr. Burdon-Sanderson's handbook (*see page* ,) 2170. Knows each of the contributors to the handbook, and has full confidence in their humanity and judgment, 2176; and while not agreeing with every line thinks there is no experiment which would not be justifiable in teaching students in pure physiology, 2175.

Legislation is unnecessary.

Regulation of Experimentation.—Is not prepared to deny that the practice of vivisection is abused abroad, 2044–5; but is not aware of any abuse of the practice in this country, and thinks therefore that legislation is unnecesary, 2042–3; thinks that the selection of experiments should be left to the teachers, assuming them to be competent, rather than be limited by law, 2171–2; believes that at present public opinion among physiologists is sufficient to check abuses, 2176. If, however, the practice in this country were assimilating to that of foreign countries his opinion as to the necessity of legislation might be modified, 2044–7.

Dr. Playfair's bill.

Agrees with Dr. Pavy in saying that if Dr. Playfair's bill were to become law it would not render illegal any of the present experiments now performed in the London schools, and he is sure that the gentlemen in charge of the laboratories out of London,—*i.e.*, those at Edinburgh, Manchester, and Cambridge would also say the same, 2075; but although it would not interfere with the leading physiologists thinks it would be an undeserved stigma on them. Sees no difficulty, however, in working it if it be required, 2186–90.

J. BURDON-SANDERSON, M.D., F.R.S.

Professor of Human Physiology at University College, London, Superintendent of the Brown Institution, and author of one part of the "Handbook for the Physiological Laboratory," 2206–7, 2209.

University College.

Necessity for experiment.

Is excluded from practice and restricted to lecturing and original research by the terms of his appointment at University College. Has been lecturer on physiology since 1866, and gives every year one course of 75 lectures, in which no experiments on animals are performed, 2651–4; each lecture lasting an hour, 2660; also goes through a practical course lasting about 11 weeks, of which five are devoted to chemical experiments; two or two and a half weeks to observations on the living tissues of dead animals, and the other two weeks to experiments on insensible live animals, 2654. Besides frogs, five or six rabbits, at the outside, are used, 2655–7; the lecture with the demonstration lasts about half an hour, 2660–1. Considers that the functions of circulation and respiration cannot be perfectly explained without these experiments, 2658–9.

The ordinary students attend both courses, 2714–5. Notice is given on the blackboard of all demonstrations forming part of the course. Experiments under anæsthetics are arranged beforehand and performed before smaller numbers, 2357.

Laboratory students.

Those who attend the physiological laboratory, are in a few instances persons of no profession, who intend to devote themselves to scientific research, 2716–22; the remainder are young medical men who stay on, after passing, to make themselves more efficient. The studies in the laboratories are connected with the bedside practice of the hospital as far as possible, 2723–5.

Animals used.

Occasionally uses cats as well as frogs, dogs, and rabbits, 2386–8. Will put in a statement showing the number of animals experimented on at University College, and the nature of the experiments, 2739–42.

Brown Institution.—Has the management of the Brown Institution under the University of London, 2623. It was founded with the purpose of investigating and of curing the diseases of animals. It has a hospital and a laboratory for research; numerous experiments are now being made there with regard to the nature of diseases, 2625–6. Considers that the knowledge thus gained must eventually tend to the diminution of both

human and animal suffering, 2626–33. The experiments with regard to sheep-pox have had the treatment of small-pox, of which it is a type, in view, 2629–33.

Sheep-pox.

Private experiments.

Vivisection is not a part of the business of the institution, some private experiments, however, are conducted in one of the rooms by Dr. Klein, 2796; others of a *quasi* private nature by Dr. Ferrier have been discontinued, 2797–800.

Supply of animals.

Keeps a small private stock of rats, guinea-pigs, and rabbits at the institution, from which Dr. Klein also takes his supply. These animals do not interfere with the reception of other animals for cure; in point of number, the rats and guinea-pigs are naturally more numerous than the patients, 2801–20. The rats and guinea-pigs are bought in the market; does not know how the cats and dogs are obtained, 2821–4.

Value of foreign research.

Extent of Practice of Vivisection.—Is acquainted with the foreign schools from the professional journals, and considers that nine tenths of our physiological knowledge has been derived from experiments performed in them, 2216–7. Believes there are more great men at work abroad than ever, 2211.

Admits that there are some things done abroad in connection with teaching and even with research which can hardly be justified, 2217; but does not think that the opinions held abroad will make progress here, 2759. Cannot give any information as to the number of animals consumed in Professor Ludwig's or in Claude Bernard's laboratory, 2735, 2743–4.

No abuses in England.

Considers that there is a general feeling of consideration for the lower animals in this country which prevents the infliction of unnecessary pain, 2285–7, and tends to secure the utmost pains being taken to get a definite result, 2227–9; does not believe there is any wanton or cruel experimentation in England, 2688.

During the last 20 years only three papers in the Transactions of the Royal Society, out of 18 or 19 on physiological subjects, have related to painful experiments on animals, 2605–7.

In all large schools there are pathological as well as physiological laboratories, 2727.

Research is becoming methodized.

Investigation, however, now goes on with greater rapidity, hence the comparatively large number of experiments, 2786–9; but it is a mistake to say that the "number of experiments will increase in geometrical progression;" on the contrary, knowledge is becoming methodized, and the number of separate facts on which it rests smaller, 2783–5. Believes that organization will tend to diminish the number of experiments, 2825.

Finds on investigation that not more than about 16 persons (names given) are now engaged in physiological research in Great Britain, 2607–12.

Useless experimentation.

Knows of one or two instances of useless experimentation by incompetent persons, gives details, 2615–7, but thinks such cases are very exceptional, and that the public performance of experiments tends to prevent their being undertaken privately, 2613–4.

Rabies.

Rabies in the dog could not be induced by starving the animal in sight of food and water, the attempt would be unjustifiable, not necessarily from the pain caused, but from the ignorance displayed; does not know of any foreign experiment so painful, 2764–70.

Starvation.

Chossat's experiments on starvation have given valuable results, but should not be repeated unless doubt arises with regard to them, 2774–6.

Needless prolonged suffering.

Thinks that in M. Paul Bert's experiment of dissecting out and irritating for six hours the pneumo-gastric and sciatic nerves of a dog, there was not a due regard to the infliction of the least possible amount of pain, 2778.

Baking and freezing to death.

Points out with regard to Dr. Legg's experiments on cats, that in no case was the temperature above fever heat, 2388. Considers that the animals baked and frozen to death by Delaroche and Berger soon ceased to feel, 2778–9.

Refers to the appointment of a French physiologist at the college for the medical education of women, 2790–5.

Is of opinion that the knowledge of the nature of processes of disease obtainable from dead-house observation may be considered nearly exhausted, it is now necessary to go to the living frame, aided by the microscope and other appliances, 2707–13.

Increased knowledge will result in better treatment.

Results obtained by Experiment on Live Animals.—Contends that the utility of physiological research is manifested not so much by its present direct applicability to disease, as by the certainty that the knowledge derived from it will ultimately be the guide to the best treatment, 2296, both in medicine and surgery, 2704–6. Refers at length to the knowledge obtained with regard to the mechanism of inflammation and of tuberculosis by painful experiments on animals, 2296–9; and thinks if as much were known of the mechanism of cancer and rheumatism, we should be in the way of doing a great deal more good. Instances, as improvements of treatment resulting from the increased knowledge obtained by experiment, the application of cold in certain stages of rheumatic fever; the abandonment of bleeding in cases of fever; the modified use of gelatine for invalids; the use of alcohol in cases of fever, *page* 8.

Tuberculosis.

Refers also to the knowledge of the causes which lead to the secondary diseases following injuries, and of the circumstances favouring the development of tubercular diseases as tending to make them eventually preventable, 2299.

Number of animals used.

In the investigations with regard to tuberculosis, extending over some years, 200 or 300 rabbits may have been used, 2737; refers to another course of research in which about 50 animals were used, 2738.

Limits of Experimentation.—The justification of an experiment depends on the importance of the object compared with the amount of pain caused, which should be considered beforehand, 2750–5; and the pain made as small as possible, 2763.

Pain inflicted for non-scientific purposes.

Coursing.

Refers to the lingering deaths of many of the rabbits snared and trapped, and contends that the amount of suffering caused by these means, and by the gunshot wounds of animals that escape is enormously greater than that of those put to death by physiologists, 2698–703. Would consider killing a hare for experimental purposes in the manner done in coursing unjustifiable, unless for an object of great importance, 2695–7.

Thinks physiological experiments should be discouraged, except in the hands of those who have been trained in a laboratory of research under skilled investigators, whom the students should assist, 2241–2.

Repetition will become less necessary.

Admits that during the last 25 years the introduction of more exact methods has necessitated a great deal of revision of results; but with the present exactitude, future repetition will be less frequent, 2781–2; it is, however, difficult to say when a fact may be considered established, 2223–4. The establishment of new facts should only be attempted by thoroughly competent persons, 2225–6.

No English physiologist would think of repeating very painful experiments which had been verified abroad, 2780. Painful experiments are only necessary in original research, 2289.

Private research.

Individual research is open to the objection that results cannot be so easily verified; it could not be well forbidden in England, and it has often produced valuable results, 2302, 2309.

Increase of practical instruction.

Experimental research has not changed its character, 2672–6, although schools of physiology are more completely organized than formerly, 2212–3; 30 or 40 years ago there was no such thing as a laboratory of practical chemistry for educational purposes in the country, 2677; there was no physical laboratory even 20 years ago, 2678; until lately the professor of physiology at Edinburgh was the only purely physiological office in Great Britain, now there are only three, 2301.

Tendency to centralization.

Believes that the growing refinement of research will necessitate the use of special laboratories and appliances, and the abandonment of private research, 2680–1, 2685; and also make experiment by students improbable, 2682–3. More efficient laboratories are desirable for the sake of producing men of higher scientific attainments, 2732–4.

Medical Education.— Thinks that medical students should be taught the application of chemistry and physics to the explanation of living phenomena, 2302; but as medical practice is at present based on clinical experience, does not desire that they should go through the physiological laboratory unless they wish to become consulting physicians or surgeons, 2728–31.

Thinks physiology should be taught to workers designing to be physiologists, not by lectures, but by association, for experiment and practical work, in schools under competent instructors and attached to public institutions; believes with such an amount of publicity and responsibility abuses would be very unlikely to occur and the verification of results would be secured, 2302–8.

Practical physiology is taught by experiment at Guy's and King's College Hospitals only, 2286–8. The practical nature of modern education is not confined to physiology, it is applied also to chemistry, physics, &c., 2679.

Experiment for demonstration.

Admits that physiologists differ in opinion on small points, but thinks there is a general agreement that painful experiments are not necessary or desirable for demonstration, 2618, 2756–62; thinks anæsthetics should be used whenever possible, 2221–2, always employs them himself, 2230.

Strychnia.

Thinks the action of the most important poisons, such as strychnia for instance, should be shown to students; no one can form a vivid conception of their action without seeing them, 2231–8; such experiments cannot be performed under anæsthetics, 2618; but the pain is of short duration; death by strychnine would be clearly shown in five minutes, 2620–2.

Not for ordinary students.

Some experiments are basis-experiments; others are for demonstration.

Handbook for the Physiological Laboratory.—The book is intended for "beginners" in research, not for students of medicine; always points this out to his class, 2239–40, 2243, 2638; the title indicates that it is for students in laboratories which are under the control of skilled physiologists, 2662–5, and makes no reference to experiments for education, 2639; it was designed to give a new start to physiology, 2214–5; and was intended as a statement of the objective basis of physiological doctrine, as well as a guide in experimentation, 2666–8. Some of the experiments are meant to be shown to students, 2640–1; others are intended, not for repetition, 2280, but as an exposition of the means by which admitted facts have been arrived at, 2642, and form the basis from which to proceed in further research, 2648–50; believes that the publication of the details of such experiments prevents their being repeated, 2643–7.

Admits that there clearly ought to have been a distinction drawn between these basis-experiments, and those intended for demonstrations and as patterns, 2372.

Regrets the mistakes made in the publication which have led to such an erroneous feeling on the part of the public, and would be glad to see them rectified, 2367–70; and his real views placed more clearly before the public than they are in the book, 2284.

Cannot say how many copies of the handbook have been sold; it is in the publisher's hands, 2364–6; the only edition is dated 1873, 2634–5.

Cannot say how many of the experiments are painful and how many not, 2748–9; very few of them can be conducted without exceptional instrumental aid, 2684; many of them have not been verified by himself, 2746–7.

Thinks the experiment in which two needles are inserted in a frog, one entering the cranium through the occipital bone and the other the spinal canal, and the heart then exposed, would give extremely little pain even if the animal were not curarised, 2253–4; bearing in mind that it was an experiment of research with a definite object, it would be absurd to use any other anæsthetic, 2256–8.

In experiment 74, in which the frog is directed to be "slightly curarised or rendered motionless by the section of the medulla," the brain of the frog should have been directed to have been destroyed, 2259–61.

Tying the jugular vein of a rabbit.

Refers to a painful experiment in which the jugular vein of a rabbit under curari is ligatured and severed, and admits that an anæsthetic also should be used, although not mentioned, 2262–5; the rabbit, however, showed no signs of subsequent pain, and would have lived if it had not been killed to observe the effects; would not dream of repeating such an experiment, 2371–6.

The use of anæsthetics is assumed.

Points out that the book was intended for physiological readers only, and that as it is generally agreed among physiologists that anæsthetics should be used whenever possible, their use was assumed; admits, however, that it would have been better to have been more explicit, 2265–73.

Vagus nerves

The division of the vagus nerves (Ex. 101) produces inflammation of the lungs, 2771; entails pain similar to that felt in that disease, and results in the death of the animal; the experiment is not intended for repetition, but as, irrespective of the handbook, some doubt has been thrown upon the alleged results, it may be necessary to repeat it, 2274–82.

Arterial pressure.

The experiment (*page* 176) in which a glass tube is introduced vertically into the aorta of a frog, is of very short duration and attended with very little suffering, as the whole of the blood is speedily driven into the tube and the animal dies, 2377–9.

Asphyxia.

The subject of asphyxia is now well understood; painful experiments to prove known facts should not be made, 2283.

Effects of curari on frogs

In ordinary doses curari does not affect the sensory nerves of any animal, but in large doses it appears to affect the central organ of the frog—gives reasons, 2380–1; refers to an experiment described in the handbook in which the heart of a frog is laid bare, and observes that the action of curari is not yet thoroughly understood; it is not treated in the handbook as an anæsthetic, as far as regards the higher animals, but is inclined to think that very little pain is felt by a frog under its influence, 2244–53, 2636–7.

Frogs.

Sensibility of Animals.—Is clearly of opinion that the sensibility of the frog is very small; admits that the evidence on the point is negative, but refers to the fact that a frog deprived of its hemispheres moves in the same way when touched as a sound frog; and points out that the smallness of its sensory system is an argument in favour of its low sensibility, 2379, 2382–5; the difficulty of getting frogs under chloroform is so great that it would be absurd to attempt it in many cases, 2378.

Deprecates legislation.

Regulation of Vivisection.—Does not consider legislation necessary, 2687, 2689; and although admitting it would not interfere with men of eminence if it ensured proper organization, fears it would stifle private investigation, 2826–7; original research by incompetent persons and some continental practices might, however, not improperly be forbidden, 2218–9, 2290–2.

Thinks that the head of a school of physiology might be held responsible for doing his best to prevent abuses, but he should not be held personally answerable for the acts of others, 2389–92. So far from it being necessary to restrain medical students from experimentation, the difficulty is to get them to work for themselves, 2669–71.

Inspection impracticable.

Does not object to publicity, 2353–6, 2358; but considers that inspection of laboratories would be impracticable, and keeping a list of the animals useless, and as regards frogs and such animals impossible, 2352; believes that the laboratories attached to public institutions would not be more beneficially controlled by law than they now are by the various managing bodies, 2311.

Dr. Playfair's bill.

Has had some conferences with Dr. Playfair, and assents to the general scope of his bill, 2220, 2293–5, 2312–3, 2686; but objects to some of the phrases as being of doubtful interpretation, and as likely to narrow the extent of investigation more than the advocates of the bill wish, 2314–6; does not object to the proposed licences, 2352.

Making a law on the subject would be [illegible]

Considers that it would be a slur on medical men to legislate against their inflicting pain on animals for scientific ends, whilst the sportsman is not controlled, 2690–3.

but would not interfere with science.

Believes that a law forbidding experiments for demonstration except under anæsthesia, but granting licences to competent persons to perform other experiments under reasonable restrictions, would not interfere with physiological science in England, 2619.

MICHAEL FOSTER, M.D., F.R.S.

Prælector of Physiology at Trinity College, Cambridge, and author of one part of the "Handbook for the Physiological Laboratory," 2208, 2210.

Concurs in the main with the evidence given by Dr. Sanderson, but would not go quite so far in the matter of legislation, 2317–9.

In England.

Extent of Practice of Experiment.—Twenty years ago there was very little physiology carried on in England; but from 1810 to 1820 there was probably as much done in England as abroad; since then there has been less, 2413.

Abroad.

Believes that research is principally confined in Germany to public laboratories, and in France to those of Paris and Lyons, 2399–400. Has no personal knowledge on the point, 2401–4; but considers that physiologists abroad are not so considerate towards animals as English physiologists, 2410.

No abuses in English schools.

Does not believe abuses exist in English schools, 2416; or in English physiological inquiry, thinks that the humanity of those concerned may be safely trusted to prevent them, 2320–1, and minimize pain, 2346–7; points out that the number of necessarily painful experiments is very small, and that generally the pain can be kept within small limits, 2343–5.

Extirpation of the kidneys.

Does not consider the extirpation of the kidneys, as described by Béclard, a useless experiment; thinks it distinctly likely to produce scientific results, 2406.

Effects of changes of temperature.

Declines to give an opinion with regard to the experiments referred to for ascertaining what temperature animals can endure, without knowing particulars, 2408–9. It is very difficult to judge whether an experiment is needless; there have, however, been such, 2405.

Objects of the book.

Handbook for the Physiological Laboratory.—The object of the book is to advance physiological science by experimental and other methods, 2414; does not believe it will tend to introduce continental methods; English good feeling will exist whether the investigators be few or many, 2411, 2415.

Use of anæsthetics assumed.

It being intended that these experiments should be performed under competent supervision, he was the less particular about inserting directions with regard to anæsthetics in each experiment, 2332; would be more careful about anæsthetics if he had to write the book again, and would state to others the additional precautions he himself takes to prevent pain, 2333–9.

The recurrent sensibility experiment was inserted to complete the section; points out that the language shows that it is on a different footing from the rest, and is not meant for demonstration, 2420; has never performed it himself, 2419.

The frog in hot water.

In putting the frog into water and gradually raising the temperature,—gives details of experiment,—directly the frog becomes uneasy, the object is attained, and the animal should be taken out, although the description does not specify this, 2421–4.

Curari.

Does not agree with Claude Bernard and the continental physiologists with regard to the action of curari; thinks there is tolerably conclusive evidence that it destroys the central nervous system; and, therefore, consciousness, gives particulars, 3123–6; at the time the handbook was written the action of curari on the central nervous system was more doubtful, 2327–9, 2331.

Uses morphia with it.

"Strong" frogs were selected in the experiment with curari, in order to better manifest the poison, 2330; witness has been accustomed to inject morphia with curari to prevent pain, 2332.

In experiments for demonstration witness performs all painful experiments, or parts of experiments, under anæsthetics, and thinks this course should always be pursued, 2338–42, 2417–8.

Legislation unnecessary.

Has no objection to legislation, but thinks it unnecessary, 2321, 2348; both as regards public and private experiments, 2393–4; and believes that the good feeling of Englishmen will prevent the necessity of legislation in years to come, 2415.

Licences.

Although physiologists might be able to indicate the *line* of their research, it would make investigation impossible if they were compelled to obtain special licences for each set of experiments; thinks, therefore, that licences should be general, not special, 2395–6.

Private experimentation.

Any legislation preventing private experimentation would be undesirable, although private experiments are necessarily growing fewer, from the growing necessity of having elaborate appliances, 2348–9; admits, however, that they should be restricted in the same way as those made in public, 2350–1.

JOHN ANTONY, M.D.

Was a pupil of Sir Charles Bell while at the Middlesex Hospital, and was selected to prepare dissections for his lectures, 2425–7, but never saw any of his experiments on live animals, 2428–32. Is now constantly occupied in dissecting with the microscope, 2490–1.

Animals vivisected and thrown on the floor to die.

Studied physiology at Paris in 1838; gives particulars with regard to the experiments (Appendix III. § 3.), 2435–40; has seen no vivisection "since the awful dose" he then had, 2582. Animals were there treated like so much inorganic matter, 2582; in some cases for instance, portions of their brains were exposed and torn or cut, and the animal thrown on the floor to creep into a corner and die, 2448. Nothing was taught by these demonstrations that could not have been learned from books, 2450; thinks nationality had something to do with the cruelty, 2583; all the English students were very indignant at it, 2437. With all their indifference to animal suffering the discoveries made by Frenchmen, even including Claude Bernarde, 2561–2, are not comparable in value to those of Sir C. Bell, 2457–9.

Private Experimentation.—Knows of some instances of experiments by young medical practitioners in private houses in the country on guinea-pigs, cats, and dogs, made from mere curiosity and without anæsthetics; believes this state of things has existed for years. Has remonstrated with the perpetrators, but cannot give details without breach of faith, 2509–28, 2532, 2592–5. Amongst others. Bischoff's experiments, tying one of the fallopian tubes and leaving the other in the guinea-pig, and cutting out the lungs of a frog without killing it, and inducing inflammatory action therein were performed; admits that Bischoff's experiment is less painful than "spaying" a sow, but considers the other experiment cruel, the web of the foot might have been used instead; the frogs might have been pithed but they were not; has seen none of those experiments himself, 2529–49; thinks legislation declaring such experiments illegal would prevent them, 2601.

Relative sensibility of animals.

Sensibility of Animals to Pain.—Believes that the capability of feeling pain and the amount of intelligence increase and diminish together, 2597–8; gives instances, 2603–4, both diminish as the order of animal becomes lower; refers to the indifference with which some animals part with their limbs, and gives various reasons and examples, and points out that the nervous systems of the lower animals consist mainly of the nerves of organic life, 2459–66, 2476–7.

Increased suffering consequent on civilization.

In the human being, in addition to a certain amount of inevitable pain, 2557, in cases of injury, a large amount of suffering arises from the hyper-æsthesia of civilization, 2550, and possibly from a delicacy of organization, resulting from successive generations of civilized life, 2553.

Has himself seen, for instance, savage women get up and carry burdens within an hour after parturition, while civilized women suffer many hours, 2552, and a similar difference exists between a racehorse and a carthorse, or an Italian greyhound and a bulldog, 2596–7; animals do not suffer from constitutional irritation, nor generally speaking from the pain of anticipation, 2554–6, although dogs appear to do so to some extent, 2602.

Signs of pain.

Crying, struggling, &c., often occur when there cannot possibly be any pain, 2558–9; considers that in the case stated with regard to the lobster cut up by a lady physiologist was no evidence to show that it felt pain, 2560.

Dogs and cats are principally used because they are high up in the list of mammals and are easily obtained; does not think they feel pain as acutely as men. Sir C. Bell's chief experiments were on a donkey, 2478–81; frogs are largely used by physiologists because their nervous system is relatively large; but it does not therefore follow that they feel pain acutely any more than it follows that a dead horse feels pain, because a recently killed and even decapitated horse will kick with great force if he be at once skinned, 2483–4; excluding intelligent animals from vivisection would exclude those most sensible to pain, but it would also exclude those most like man, 2599–600, and such likeness is often essential in experimenting, 2482.

Considers that observations of the vital processes in the lower animals are advantageous to human beings, 2443–4; and that the functions of individual nerves could only have been ascertained by vivisection; gives examples, 2445–6.

Licences.

Regulation of Vivisection.—Thinks that licences should be granted by the Secretary of State or some public officer but to those who have shown great aptitude in physiology or cognate sciences, 2444, 2472, and for some fixed period only, 2507, and also for some fixed place subject to inspection, 2500; is not prepared to go into details, but thinks there would be no difficulty in restricting the licensee in such a way as to stop cruelty, 2449, 2474–5, and believes that any one who ought to receive a licence would, in the course of acquiring the requisite amount of knowledge, become recognized as a fit person, 2470–3; believes that heads of schools would for the sake of the general good submit to receive periodical licences, 2558.

Objections to public laboratories.

A laboratory, whether at the licensee's residence or in a specially appointed place, should be open to the experimenter and the inspecting officer only, 2491, 2567–70; gives details on the subject, 2501–4, and thinks private workrooms are preferable to public laboratories, because discoveries are made in private, and discoverers are often jealous, 2447, although there are many exceptions, 2563–7.

Inspection of laboratories.

Thinks inspection by a specially appointed qualified official, generally approved of by the profession, would be preferable to any system of experiment before the public, 2444, 2454–5, the inspector to see that certain specified regulations were carried out, 2453; thinks the inspecting official should be a member of the medical profession, but not a skilled physiologist, and that such a man would have little difficulty in saying whether an undue amount of suffering were caused, 2496–9; admits that if an inspector should be of opinion that an eminent physiologist were cruel, professional opinion would probably be on the side of the physiologist, but still inspection would be effective in stopping the licences of cruel young men who might have obtained them, 2505–7.

Are unnecessary.

Experiments for Educational Purposes.—Does not consider experiments on live animals at all necessary for demonstration in medical education; the phenomena produced by strychnine, for instance, are so peculiar that they could not be mistaken even if never seen before; gives other reasons, 2450–2, 2485–93; admits that the fact of some few persons going to operating theatres from morbid curiosity is no argument against public operations, 2571–3; but thinks the dissecting room is a fearful trial to the young student, although getting hardened to it does not render them less tenderhearted, 2574–7: contends that frequently seeing experiments on live animals blunts men's feelings with regard to such experiments, although not rendering them less tender generally, 2578–81; considers that public demonstrations by vivisection are useless and demoralising, and should be forbidden, 2444, even under anæsthetics, 2450.

Demoralising effects of experiments for demonstration.

Sir C. Bell.

Miscellaneous.—Bell was said to be most kind and feeling, and to have limited pain as much as possible, 2430–4; he was very proud of his experiments, and insisted on them as evidence of his great discoveries; cannot reconcile any assertion to the contrary with his own observation, 2584–9; believes Sir C. Bell's remarks with regard to the wanton experiments made in his day referred to Majendie's, 2590.

Believes that vivisection is extending in England, 2441–2.

Anæsthetics.

The majority of experiments at present can be performed either wholly or partly under anæsthesia, 2456–8.

Does not deny that physiologists make wanton experiments, but believes that they are seeking good objects, 2591.

WILLIAM RUTHERFORD, M.D.

Professor of Physiology at the University of Edinburgh, and formerly at King's College, London, 2828–9, 2901.

Visited Berlin 11 years ago, and Leipzig 5 years ago, to gain physiological and medical knowledge, not then obtainable in England, 2968–75; went through a special private course of experimental physiology at Berlin, 2867, 2987.

Medical School at Edinburgh.—The medical school at Edinburgh is the largest in the kingdom, 2830; physiology is taught by a course of lectures, and by a practical course embracing microscopic and chemical studies, and a few experiments on living animals, 2831; the larger number of experiments are on the dead tissues, the chemistry of digestion, &c., 2869–70.

Expenditure of animals.

For the systematic course uses two dogs, three rabbits, and a considerable number of frogs; in the practical course not more than six rabbits and a considerable number of frogs, 2990–2, 3838; for research used last year about 40 dogs and 8 rabbits, no cats or guinea-pigs; the number of dogs is exceptional; in the whole five years when in London did not use more than 10 dogs, 2993–5.

In both courses the dogs and rabbits are put under chloroform, chloral, or opium, and the frogs, generally, not always, pithed, 2832–6, 3839; the frogs not pithed are used to show the action of poisons, 3837.

Number of painful experiments.

Experiments for original research are performed either by witness or his assistant, or by some one under their immediate superintendence, 2840; on the average about half the experiments are painful, 2841–6.

Vivisection by students.

Has never heard of private vivisection by students, 2855; and during his 10 years' experience has never known a student desirous of undertaking an original research; the only experiment students perform at Edinburgh is that of demonstrating the circulation of the blood under the microscope, 2997.

The new laboratory.

The new buildings at Edinburgh are designed to give greater convenience for experiment, but certainly not for any increase in the present amount of vivisection, 2890, 2892–3.

Vivisection has increased in England with the introduction of practical instruction in physiology and with the increase in original research, 2848.

Germany.

Experimentation Abroad.—Has no personal knowledge of inhumanity abroad, 2754; both at Leipzig and at Berlin vivisection was conducted most humanely, 2914, and the instruction thus conveyed ample, 2915. Did not see any reckless vivisection abroad, 2989; but thinks the Germans are somewhat less careful as regards the repetition of painful experiments than the English, 2983–6.

Noticed that in some parts of the continent there was less delicacy in the treatment of human patients than in England, 2851, 3001–4. Considers the tone of English feeling with regard to the infliction of pain higher than it is abroad, 2850–4.

Cannot give any information as to the number of animals consumed in laboratories abroad, 2998–3000.

Action of rhubarb on the liver.

Experiments for ascertaining the Action of Drugs.—Considers the experiment on the biliary secretion of the dog referred to as very important as demonstrating the effect of rhubarb and colchicum in stimulating the liver; in this experiment the animal was placed under curari, and a tube inserted in the bile duct to receive the secretion, respiration being maintained artificially, 2002–8, 2959, 2961, 2964; before these experiments the action of rhubarb was involved in doubt, 2955–6. Considers that the action of these drugs on the dog is a guide as to its probable action on man, 2959, 2962, 2965–7; points out the advantage of this knowledge in their treatment for a sluggish state of liver and for gall stones, 2956, 2958–9, 2963; and contends that the knowledge gained by such experiments is calculated to prolong human life and diminish suffering, 2960. The operation took about half an hour, and the dog was kept eight hours alive subsequently; the wound would be opened two or three times to inject some substance into the bowels, and then reclosed; does not consider the experiment involved great pain, 2917–31; chloroform or opium in any form would have retarded the action of the liver, and therefore could not be used, 2912–3; about 30 experiments were previously performed on the same subject under chloroform, 2932; such an experiment should not be repeated for teaching purposes, 2943.

Uses of the knowledge of its effects.

Calomel.

Whether the action of calomel on a man is similar to its action on a dog is a moot point, 3012–4.

Podophyline.

Was himself satisfied with the results of six experiments when investigating the properties of podophyline, 2945–6; the first experiment on a rabbit giving no result, 3020; is aware that it might be urged that the use of curari interfered with the result, but believes that the reasons against its doing so are valid, 3021; admits that another set of experiments resulted in different conclusions being arrived at, and that, assuming a doubt to exist, repetition might be desirable, 3016–7.

Repetition of Experiments for Verification of Results.—Experiments should be repeated if there be any doubt as to the result, 2847; but the number of times an experiment should be repeated is a difficult question, and can only be left to the discretion of the person licensed, 2945–7; a course which would, however, work very differently with different individuals, 2948.

Painful experiments are necessary for the discovery and verification of facts, 2856–7; but only highly qualified men are competent to undertake them, 2863–6.

Unnecessary in the higher animals.

Experiments for Demonstration.—Repetition of experiments is essential in teaching, and although painful experiments on the dog or higher animals are unnecessary, 2940–2, they are necessary on frogs in order to show the action of poisons, 2858–9, 2862.

Strychnine.

It is desirable that students should see the action of strychnine, which can be shown in five minutes on a frog, 2860–1; in order to recognise its effects on the human subject, and to understand tetanus, 2976–9; entirely differs from those who think that written descriptions of the action of strychnine, &c. are as good as ocular demonstration, considers, on the contrary, the latter essential, 2980–2.

It is even more essential that some of the experiments demonstrating the mechanism of the body should be shown, 2981.

Students.

Believes that students would not tolerate experiments unless anæsthesia is produced and maintained; gives instances, 2898–900.

Points out that under an organized course of practical instruction the number of experiments is minimized, 2867–8; as one animal is sufficient for the whole class, 2891, 2894–5.

Bernard's opinion.

Curari.—Bernard believed that curari only affected the motor nerves, recent experiments, however, seem to indicate that it affects the sensory system also, 2939; and is to some extent an anæsthetic, 2909–10, 2934.

Is not aware of any facts tending to show that curari affects differently different classes of animals, 2911; there are accounts of the death of human beings poisoned by curari, but cannot give details, 2937–9.

Admits that curari might be given to prevent manifestation of pain and expressions of disapproval by the students, but thinks that an anæsthetic, about which there is no doubt, should always be used in experiments for demonstration, 2933–5; in some cases chloroform and curari might be used conjointly, 2935*a*–6; opium, chloral, and chloroform all destroy pain if given in sufficient doses, 3010–1.

Sensibility of animals.

Infers from observations—gives details—that the sensibility of animals differs greatly, and that of frogs is much below that of higher animals, 2871–2.

Legislation is unnecessary.

Regulation of Experimentation.—Believes there are no such abuses as are popularly reported to exist, and thinks legislation unnecessary, 2953; and that the present popular feeling is based on ignorance of what is really done, 2849; but believes that legislation, not interfering with physiological education or with research by competent men, would not be objected to by physiologists, 2916.

Vivisection of the domestic animals.

Forbidding the vivisection of the domestic animals would be a great blow to medical and physiological education; many experiments could not be shown on frogs, the experiments relating to the pressure of the blood for instance, 3005–9; thinks both dogs and rabbits are necessary as well as frogs, 3018–9.

Licences inspection.

If legislation is undertaken, thinks granting general licences to competent persons the best course to adopt, 2882. Would not object to the Inspectors of Anatomy being empowered to inspect these experiments, 2951–2, and report to the licensing body what the experimenters were doing, 2874, 2883; does not consider a lay element necessary to the licensing or inspecting bodies, medical men are as humane as others, 2953.

Record of experiments.

There would be no hardship in requiring a record of all experiments to be kept; most experiments are already recorded at Edinburgh, 2884–7, 2949–50; such a record would tend to stop the proceedings of incompetent persons, 2888.

Dr. Playfair's bill.

Objects to Dr. Playfair's bill because it forbids all experiments for demonstration under pain of fine and imprisonment, 2877–9; even if those under anæsthesia were allowed it would still be objectionable not to be able to show the action of poisons on frogs, 2881; except in this respect the bill would not interfere with things at Edinburgh, 2882; but passed as it stands it would drive students abroad, 2880; considers that Dr. Playfair's bill is complex and indefinite, and prefers Lord Henniker's, 2882; which would have prevented experimentation by unfit persons without interfering with competent men, except as to the licensing, 2875–6. Objects to the power of granting licences being vested in a Secretary of State; thinks placing it in the hands of the councils of the Royal Society and of the Colleges of Physicians and Surgeons preferable, 2873–4.

Lord Henniker's bill.

WILLIAM TURNER, M.B.

Professor of Anatomy at the University of Edinburgh, 3022; one of the editors of the Journal of Anatomy and Physiology, 3099.

Has been lecturer on anatomy at Edinburgh for 21 years, and has the largest class in Great Britain, the number of students in it being upwards of 450, 3069–71; from one third to one half of whom also attend the lectures on physiology, 3072–3; there are no experiments on live animals in the anatomy class, 3023.

Practical demonstration necessary.

Necessity for Experiments on Live Animals.—Points out that although the structure of the body may be both verbally and graphically described, dissection is essential, 3092–5, and that there is a general agreement among scientific men that similar practical teaching is absolutely necessary as regards physiology, 3097–8; most recent discoveries have been made in Germany, where the best practical instruction is given, 3100–1.

Humanity of physiologists.

Resorts to experiments on living animals himself only when it is of paramount importance, believes other experimenters are equally careful to avoid giving pain, 3079–80; refers to the reluctance with which Sir Chas. Bell and Dr. Jones performed experiments, 3025, 3079; and believes English experimenters generally are humane, 3139–40.

Objections were made to investigation by vivisection in Harvey's time, 3025, 3089.

Extent of practice of experiment.

There is more vivisection now than formerly, because teaching is more thorough and practical, and there are more workers in the field, 3090–1; but although practical physiology has only been taught in the schools of late years, many eminent men experimented for themselves in their early days, gives instances, 3141–5.

Functions of the spinal nerves.

Results arrived at by Experiment.—The supposition that the functions of the anterior and posterior roots of the spinal nerves were respectively of a motor and sensory character, although originally suggested by an anatomist, Mr. Alexander Walker, of Edinburgh, was

Turner, William, M.B.

definitely proved by Sir Chas. Bell's experiments, and the respective attributes of each ascertained by his and Majendie's experiments, 3025.

mproved method of igature.

Refers to the improved curative methods which have been resulted from vivisectional observation, instances the knowledge derived from Dr. Jones' experiments on horses and dogs as to the best form of ligature and the best means of avoiding secondary hæmorrhage and of obliterating arteries, quotes various authorities on the point, 3025–7; refers to the value of Dr. Hunter's experiments with regard to aneurism, 3027; also to the experiments by Drs. Hope and Williams with regard to the sounds of the heart by which certain diseases can now be recognized; refers at length to the discovery of vaccination by Jenner, and the important discoveries which have followed Galvani's investigation on frogs with regard to animal electricity; all instances of the valuable results flowing from experiments on animals, 3027–8.

Aneurism.

Sounds of he heart.

Functions of the periosteum.

Asphyxia.

Diabetes.

The reproductive functions of the periosteum and method of the repair of bone have in great part been arrived at by experiment, 3125; the whole subject of asphyxia has been investigated by experiment on the lower animals, and results obtained which could not otherwise have been arrived at, particulars given, 3121–4; that diabetes is not a disease of the kidneys, was ascertained by experiment, 3126.

Increased knowledge of the various vital functions, &c.

Circulation of the blood.

Lymphatic system.

Our present knowledge of digestion, of the secretions, of the action of the nerves on the glands, of the action of the vaso-motor and of the inhibitory and other nerves, of the functions of the kidneys and reproductive organs could only have been ascertained by vivisection, 3081–8; with regard to the discoveries which have followed from vivisection, refers to the discovery of the circulation of the blood, &c., observes that although the discovery was led up to by the structure of the different parts of the circulating system being made known by anatomists, the functions of the heart and arteries were discovered by vivisection, by Harvey, and that of the capillaries by Malpighi, 3025. The discovery of the lymphatic system by Asellius in 1622, and of its course and objects by Pecquet in 1649, were results achieved by vivisection, and the matter is being further pursued by Dr. Sanderson and Dr. Klein, 3025.

Considers that the foregoing results, like many others not mentioned, could only have been obtained by means of vivisection, 3057–64.

Most experiments can be rendered painless.

Use of Anæsthetics.—A large proportion of experiments, including those for research, can now be performed either wholly or in part on animals deprived of sensation by anæsthetics or otherwise, 3029, 3034–6; nearly all the experiments performed by Harvey would be now rendered painless, 3065–8.

Extent and Limits of Experimentation.—Experiments before classes should be very limited in number and might generally be performed under anæsthetics, 3030–3.

Experiments on the nerves

Some experiments, such as those on the nerves, must cause pain, but anyone with ordinary humane feelings will endeavour to minimize it, 3138; it is indeed necessary that experiments should be performed with as little disturbance to the animal as possible, from undue disturbance experiments by incompetent persons may easily give misleading results, 3153–5; painful experiments should be performed by competent persons only, 3039–40; and those demonstrating facts about which there is no doubt should not be repeated, 3037–8.

Vivisection by students.

Here and there a student may occasionally vivisect animals, but it certainly is not a practice among them, 3074–6; knows nothing of the experiments by students referred to by Mr. Mills, 3130–3; as a rule medical practitioners have neither time, nor he believes inclination, to vivisect, 3077–8.

Alleged vivisection of a lobster.

No one knowing anything of elementary physiology would have raised a charge of cruelty on the ground that whilst a lobster was being cut it moved its limbs, 3108–9.

Regulation of Vivisection.—Admits that there is nothing now to prevent any man from hiring a room and performing any experiments he chooses, as long as he does not contravene the Act for the Prevention of Cruelty to Animals, 3115–7.

Difficulty of defining competency.

Fears lest legislation may check the progress of discovery, 3055–6; and is of opinion that no restriction should be placed on competent persons, but does not see how or by whom competency is to be determined, 3127–8; although the professors of the various medical schools would know most, they would not know all, who were competent to undertake such experiments, although there are very few such, 3041–7; is not prepared to admit that experiments on living animals are performed by incompetent persons in this country, 3129.

Turner, William, M.B.

Objects to class legislation against physiologists.

Deprecates legislation with regard to experiments on living animals, on the ground of the difficulty of defining whether an animal is or is not "living," 3048–9; a pithed frog, for instance, although virtually dead might, as regards some of its organs, be considered "living" for some time, 3113–4; also objects on the ground that it would restrict vivisection for scientific ends, but not castration, tail-clipping, ear-notching, and other vivisection on the farm, 3050; admits that it is to the interest of the farmer to injure the animal as little as possible, but points out that it is also of the greatest importance to the physiologist that his experiment should cause as little disturbance as possible to the animal, 3134–7; does not advance the argument as to what is done on farms as tending to justify vivisection by unskilled persons, 3156–8, but as desiring to point out that any legislation restraining scientific experimentation would be class-legislation, and leave untouched similar things when done by unscientific persons, 3102–3.

Legislation might prevent the speedy detection of poison.

Limiting the right to perform experiments to competent persons would prevent a country practitioner, for instance, from testing substances suspected to contain poisons by giving them to animals, although he might not be able to detect them by other means, 3051–4; thinks such questions should be dealt with at once and on the spot, 3118–20.

Inspection of laboratories undesirable.

Deprecates the inspection of physiological laboratories not because it might be looked on as a slur on the profession, but because it might impede scientific discovery, 3146–52; and points out that if placed under the inspection of unscientific persons of the most undoubted respectability and good faith, they would probably make most unfounded charges from ignorance of the subject, 3110–1.

Inspector anatomy.

Considers that there is no analogy between the duties of the inspectors of anatomy and the suggested inspectors of physiological laboratories. The duties of the inspectors of anatomy are simply to see that the subjects for dissection are properly come by and properly buried when done with, 3104–6; an inspector of anatomy could not control the dissections, it would be placing a man without special knowledge to be a judge over experts, 3107; an Act for the physiologist parallel to the Anatomy Act would provide and regulate the supply of live animals for experiment, and see to their removal after being used, but would not interfere with what experiments were performed on them, 3159.

JAMES CRICHTON BROWNE, M.D.

Medical Officer of the West Riding Lunatic Asylum, 3160.

Nitrite of amyl.

Pycrotoxine

Has for 10 years given attention to the subject, 3161; has performed two series of experiments, one not involving destruction of life to ascertain the action of nitrite of amyl, and one with regard to pycrotoxine, the essential constituent of coculus indicus, 3163; 46 animals in all, gives details, were operated on, 3164–6; was successful in discovering an antidote, chloral, for this poison, 3163; no opportunity of testing it on human beings has yet occurred, 3167–8; witness has been denounced for this cruelty, although pycrotoxine is much used for poisoned wheat, in each case the animal dies in convulsions, 3218.

Dr. Ferrier's experiments.

Dr. Ferrier's first series of experiments were performed at the asylum, and comprised the removal of a portion of the top of the animal's skull, and the application of electricity to the convolutions of the brain. They were all under anæsthetics, and the animals were killed directly afterwards, except three, in which the hemispheres had been removed; the longest experiments lasted six or seven hours, 3169–78. In all, 29 animals were experimented on, of which five died from the anæsthetic, 3178; gives details as to publication of the results, and repetition of the experiments, 3179–82. All the experiments were painless, 3221–2; including one in which a partial recovery was permitted to solve a doubt, 3193–4.

Their objects and uses.

The object in view was to throw light on the brain and nerve diseases with which the asylum, which contains upwards of 1,400 patients, is concerned, 3195–6, and the knowledge thus obtained has been found of great service in the diagnosis of brain diseases, 3217.

Excitation of the brain of a cat.

It is true that a cat under experiment "uttered long continued cries, screamed, and gnawed its own legs, &c.," but it was under deep narcosis, and only performed these movements when the brain was excited by the electrodes, 3189; chloroform was given far more freely than would be safe in the case of human beings, 3190–1; entirely denies that it was insufficiently administered, 3184–5.

The statement that another cat was "only partially narcotised" is correct, but deep narcosis is all but death; chloroform acts first on the sensory nerves as in cases where it is inhaled for neuralgia, 3192.

Signs of pain.

Refers in detail to the important and interesting results arrived at, 3213–6; and points out that actions, usually regarded as manifestations of pain, can be produced in the human being under mesmerism without the patient knowing anything of the matter on awakening, 3197–204. Refers to cases in which consciousness has been retained during fits, and in cases of paralysis—gives details,—although no sensation of pain accompanied the signs which usually are manifestations of it, 3217–8.

Paralysis.

Mesmerism.

Is aware that it is argued that both under mesmerism and under chloroform sensations may be felt, but forgotten, but points out that such an argument is not capable of proof, 3206–7; refers to the diverse effects of chloroform on human beings, and contends the phænomena produced are independent of sensation, 3208–12.

Does not know of any other private laboratory or private experimentation, 3182*a*–3.

Thinks inspection of private laboratories would be impracticable, but would be glad of some legal sanction for experiments, 3218–24.

DAVID FERRIER, M.D.

Professor of Forensic Medicine at King's College, and Assistant Physician at King's College Hospital, London, 3225–6.

Has been a lecturer to classes for about five years, 3296; the number in the class is about 40 or 50, 3298.

The practice of experimenting on animals does not harden men's hearts. Some experimenters are among the most humane men witness knows, 3249–50.

Painful experiments should be made under anæsthesia either wholly or in part, except as regards those portions in which it would interfere with the result, 3245–8; always endeavours, himself, to minimize pain, 3230–3.

Experiments for Demonstration.—Practically, all experiments for demonstration can be performed under anæsthesia, 3234–5, 3244; as they are at King's College, 3297, 3353.

Action of poisons.

Thinks it essential that the action of poisons should be shown to students so that they may recognise their action in the human subject; anæsthetics cannot be used, but the experiments are of short duration, 3237–42, 3244, 3299; such knowledge cannot effectually be communicated by oral instruction, 3303.

In experiments with poisons, witness only uses those which have marked characteristics and act speedily, such as charcoal vapour, strychnia, &c.; uses frogs, rats, and sometimes birds, rabbits, and guinea-pigs, 3401–5.

Induction of disease.

Experiments for the induction of disease are from their duration unsuited for demonstration, 3243–4.

Neither at King's College nor elsewhere in England are animals "crucified sometimes for several days," 3333–8; has never seen any "frightful" experiments before students, or anywhere else, 3351–2; the students in either London or Edinburgh would not tolerate such things, 3339, 3356–7; on the contrary they have a repugnance to experiments even under anæsthesia, and would rebel if painful experiments were used for demonstration without it, 3340–4, 3354–5. Thinks it is libellous to say that medical students as a body have "maleficent tendencies," 3345–50.

Good feeling of medical students.

Experiments at the West Riding Lunatic Asylum.—Details the method of performing the experiments at Wakefield with regard to the functions of different portions of the brain, 3227–9. In these experiments æther or chloroform was in all cases administered at intervals, but no signs of pain were observed during the time its administration was suspended, 3363–4; in some cases in seeking to keep the animal unconscious it was overdosed and killed, 3383–6.

Anæsthetics were always used.

Experiment on the dog.

In the experiment on the dog in which one hemisphere had been entirely removed, witness was ultimately inclined to attribute its barking to a sense of pain, 3365–6; observes that such an experiment need not be repeated, 3374; but points out with regard to this and other experiments referred to, that a certain apparent consciousness is not inconsistent with entire insensibility to pain, 3367–72, 3375–7, 3379–82; and that just as a frog deprived of both hemispheres, and therefore incapable of feeling, may be made to croak by stroking its back, so the dog may have been caused to bark without feeling any pain, 3413–8.

Signs of pain.

In the human being a part of the skull may be removed and yet not the slightest pain be felt, 3377; assuming that pain was caused by the stimulus it would

cease when the stimulus was taken away, and would be as transient as the pain caused by a pinch to a man asleep, 3408–12.

Experiment on the cat.

The experiment on the cat "with and without chloroform" was the means of proving that the non-manifestation of pain was not caused by the action of the anæsthetic, 3378.

Does not believe that in these experiments pain was produced by the action of the stimulus, although it induced the signs which usually imply pain, 3406–7; adverts to the fact that under chloroform consciousness returns before sensibility to pain, and often remains while sensibility is lulled, 3427–30; and that it is said that patients observe what takes place during an operation, and yet feel no pain, 3431–2; refers to the fact that in a mesmeric state persons will rationally answer questions, and yet be entirely insensible to bodily pain, 3419–23.

Consciousness may exist with complete insensibility to pain.

Validity of argument by analogy.

In arguing from experiments on animals as to the functions of the human brain thinks that if pathology is in harmony with physiology the results may be trusted, 3387–8; and adverts to the fact that the brain in the monkey tribe is very like the human brain, 3381. Believes that in the main his conclusions are accepted by physiologists, 3387.

Experiment on a human being.

An experiment of a like nature was tried on an Irish servant whose brain was exposed, and the results were found to be the same; the patient died, it is said from disease, 3390–1; entirely objects to experiments on human beings but, for the sake of accumulating facts and advancing knowledge which may mitigate human suffering, thinks the sufferings entailed on animals are not excessive, 3392–7.

Extent of Practice of Experiment.—There are very few physiological investigators in England, but they are for the most part eminent men, 3256–9. Besides the laboratory at Wakefield, where much good work has been done, and his own, does not know of any private laboratories, 3327–31.

Experiments on living animals have sometimes been necessary to convict criminals, 3300–2.

Lectures at the London Institution.—Entirely denies that at the lecture with regard to the functions of the brain delivered at the London Institution and referred to by the Secretary of the Society for the Prevention of Cruelty to Animals there was any attempt to give a comic aspect to the phænomena described, gives details, 3274–95; there is no foundation for such statements, the managers of the institution were very anxious for him to lecture again in the same season, and subsequently, 3314–9; cannot recollect anything in his lecture that could be construed into "a joke" about the stupidity of the monkey, 3358–9; nor can he recollect saying that he was afraid to say on how many cats he had repeated the experiment, 3360; he had then experimented on about 100 animals altogether, 3381; nor did he observe any laughter in the audience, 3362.

No attempt was made to give a "comic" aspect to the facts described.

Regulation of Experimentation.—Experiments by ignorant or incompetent persons are not likely to be of any use, 3260–1; would, himself, have the greatest abhorrence of any man undertaking painful experiments without being convinced that good would result, 3426; but thinks that the majority of mankind may be trusted not to make such experiments unless some good can be got by them, 3400.

Experiment by incompetent men is unlikely.

"Cruelty to Animals" Act.

Approves of the law for the prevention of cruelty to animals; thinks any infringement of its provision, under the plea of scientific experiment, should be judged on its merits, 3269–71, and that a law drawing a clear distinction between experiments for research and the "cruelty to animals," aimed at by Martin's Act, is desirable, 3273.

The licence system

Considers that granting licences on the certificate of responsible and known persons would, perhaps, be the best compromise, although it would be objectionable in witness' opinion, 3311; believes that there is no law at present to prevent a man, whether competent or not, practising medicine or surgery, if he likes, 3312.

would not greatly interfere with research.

Thinks a system of granting licenses to competent persons would not interfere to any great extent with original research, if not coupled with inspection and the necessity of keeping a record of experiments, 3272.

Objects to inspection of laboratories.

Objects to any kind of inspection, 3272; is strongly opposed to the proposed inspection of physiological laboratories, 3320–1; considers that inspection by competent men even would be unsatisfactory, and by incompetent men it would be useless, 3323–5; experiments would often be left unperformed, on account of the trouble of communicating with the inspector, 3322.

Ferrier, David, M.D.

Contends that a knowledge of facts which might appear to an inspector most insignificant may be, and often are, pregnant with results of world-wide importance; for instance, Galvani's observation, that a frog's legs twitched under certain conditions when touched by two metals, 3424; and thinks for this reason the control of an inspector very undesirable, 3425.

Objects to licensing places.

Objects to experiments being allowed only in licensed places; many investigators live in the country, and would be debarred thereby from experiment, 3326–7.

Difficulty of deciding as to competency.

Is not opposed to a restriction being placed on incompetent persons, if it can be decided who is incompetent; but thinks there should be no restriction placed on men of ability, although not prepared to say how ability could be tested, 3262–8; considers a student of psychology, for instance, should not be restrained from such experiments, 3264; although possibly not up to a medical standard of competency, 3395, 3399; it would seem, however, necessary to have some special examination as a test, if the system of licensing persons were adopted, 3304–10.

Thinks the difficulty of fixing a standard of competency insuperable; that legislation limiting experimentation to competent men would consequently be a restriction on original research, 3251–4; has no other objection to legislation, 3255, 3262.

GEORGE HOGGAN, M.B.

Late H.M. Indian Navy, 3433, and formerly Demonstrator of Anatomy, 4198, 4206; and subsequently engaged in teaching separately in Edinburgh, 4204.

Has acted as assistant in a laboratory, 3434, and tried three or four experiments himself, but never got further than giving the anæsthetic, as the animals died under the anæsthetic, and witness consequently resolved not to try again until he had learned how vivisection was done, 3471; knows nothing from personal observation of London physiological laboratories, 4101–3.

Testing a new theory by experiment.

Having devised a new mechanical theory for respiration, when demonstrator of anatomy at Edinburgh, witness was advised by Dr. Handyside and other medical gentlemen to test it by experiment on the live animal, 3472–8, 4022–5; he was then within about a year of taking his degree, and had received all the instruction in anatomy and physiology which was necessary for taking a degree, but felt, nevertheless, incompetent to undertake such experiments, 3490–506; although as his theory was based on the contention that the action of the muscles in respiration was generally misunderstood, 4024, it could have been tested under chloroform, 4026–33.

Will not pronounce an opinion as to whether it was usual at Edinburgh for the professors to encourage young men who showed an aptitude for original research, although aware that they award gold medals for some of the theses which are sent in before attaining the M.D. degree, and which very usually treat of some matter of original research, 3507–27.

Vivisection by students.

Believes other students beside himself were advised to experiment on live animals, and that there was in the years 1867–72 considerable private experimentation among the students at Edinburgh, with the concurrence of the lecturer, Dr. Handyside; refers to a student who had made 10 or 15 experiments on cats, 3479–85; thinks anæsthesia was not used, as he was recommended to avoid cats, because they squalled and scratched when cut, 3480, 3486–9, 4209–24; believes that the students at Edinburgh undertook experiments whenever they thought any theory could be proved or advanced by that means, 4104–6; they would also get animals and open them, in order to see the heart beat, 4212.

Cats.

Cannot recall names and details, but references to private experimentation were made to him in conversation, dozens of times; fears it would be as useless to seek information on the point as to inquire into freemasonry, 4225–8.

Experiments with strychnine.

In one instance saw galvanism tried in a cellar, but not by a medical man, as a cure for poisoning by strychnine, it failed, 3462, 3465–9.

Requiring original remarks in theses tends to increase vivisection.

Deprecates the practice at Edinburgh of requiring theses, containing original remarks, before taking a degree, as a fruitful source of vivisection; thinks the great frequency of the practice in France is due in part to the University of France requiring such theses, 4238; but admits that number of theses at Edinburgh on experimental physiology is relatively small, 4242–3.

Prolonged experiment on the nerves of a curarised dog.

Reads a translation, giving in detail Paul Bert's observations in 1869, 4111, 4235, on a curarised dog, in which several of the principal nerves were successively laid bare and tied, and subsequently excited by galvanism, 4111, the dog being meanwhile kept alive by artificial respiration. After 10 hours the temperature fell, and the next morning the dog was found dead, although the artificial respiration machine still worked. The results arrived at were chiefly that contraction of the bladder was effected through the intervention of the sensory nerves, and that sugar was found in the saliva as well as the urine, 4109–11, 4140–1.

Hoggan, George, M.B.

possible reflex action of the muscles.

Admits that according to the received theory with regard to reflex action the results obtained by the action of the sensory nerves may have been unaccompanied by sensation, but has doubts as to the correctness of the received theory, 4143–53.

"Atrocious" sufferings of the dog,

Considers that tying the nerves would cause great pain, 4229–30; refers to the difficulty of getting at the splanchnic nerve, and the intense pain it must, he believes, have caused; is of opinion that in one form or another experimentation was being carried on during the 10 hours, 4165–9, and that during the whole of that time and until death surpervened excruciating suffering must have been endured by the animal, 4231–2; and if it had not died no doubt the experiments would have been resumed on the next morning, 4196–7; considers that the intelligence and sensitiveness of the animal remained intact, and that its sufferings were the most atrocious that the imagination of man could conceive, and the result trivial in the last degree, 4111–4. Does not for an instant suppose that Paul Bert considered curari an anæsthetic, 4154–6.

insignificance of the results.

Points out that in many persons contraction of the bladder may be produced by the pain given by a pinch; thinks obtaining the same result by such an immensity of pain a wholly inadequate result, 4163; does not consider the appearance of sugar in the saliva in induced diabetes a fact of much importance, 4162; considers the fact that the pneumo-gastric and sympathetic nerves remained intact as an instance of the previously known but curious action of curari in attacking one nerve after another as the dose is increased, 4157–61, and that it proves that the dose of curari in this experiment was small, an important fact, considering what its action, when given in small doses, is, 4161.

Thinks the translation is perfectly fair, and that his own remarks on it would be justified if ten times stronger, 4170–1.

Extent of Practice of Experiment.—Professor Rutherford's experiments show the progress experimental physiology is making in England; formerly one had to go to the continent to get a knowledge of the practice, 4203, 4205.

Considers that the course of experiment in England and abroad is much the same, 3459–61; and that such experiments as Paul Bert's will certainly be undertaken in England unless they are forbidden; it is for the British people to say if such things shall be done here, 4164.

Has found physiologists, especially abroad, among the kindest of men, but with an entire want of feeling with regard to the infliction of pain, 4244.

"Criminal" repetition of painful experiments.

Thinks the repetition of the experiment, described by Claude Bernard,—in which it is shown that irritation of the chorda tympani produces an increase of secretion in the glands,—criminal, although in the first instance it was a valuable, as well as a severe and painful, experiment, 4034–51; has never seen it performed under anæsthetics, believes they might affect the result, 4048–9.

Action of certain drugs on the livers of dogs.

Considers the experiment in which a glass cannula was inserted in the bile duct of dogs, who had been kept fasting for 18 or 19 hours, in order to arrive at the action of certain drugs, useless and cruel in the extreme; refers to the intense pain produced in the human being by gall stones, 3464; and thinks this experiment on the dog would, for the first six or eight hours under curari, give even greater pain, 4052–61; adverts to the experiments by which it was proved that mercury had no effect on dogs, and points out that the result is simply the knowledge that the effects of a certain drug on a dog are *not* the same as its effects on a man, 3464.

Knowledge of tubercle not advanced by experiments.

Doubts, in spite of the number of experiments, whether any better knowledge of what tubercle is, has been gained during the last 30 years; points out that M. Crocq has proved that M. Villemin's theory, which was previously accepted, is erroneous; thinks the experiments prove rather what tuberculosis is not, than what it is, 4134–9.

Bernard complains that vivisection is undertaken by incompetent persons, and that science is thereby encumbered with a mass of contradictory results, 4238, 4241.

Often insufficiently given.

Anæsthetics.—Thinks anæsthetics do more to lull public opinion than to mitigate the sufferings of animals; first, because often if given thoroughly they would kill the animals before the experiment could be concluded; and secondly, because they require an assistant to be specially told off to keep them up, 4107–8.

Morphia.

Quotes Claude Bernard's opinion that the action of morphia is "stupéfiant," and produces immobility, but does not suspend sensibility, 4133. Maintains that under morphia or opium pain is felt as long as the cause remains, but forgotten when it is withdrawn, 4184–93. Points out that the dog referred to by Bernard cried when pinched, quotes passage on the point, 4133, 4194–5.

Curari.—Is as fully convinced that curari is not an anæsthetic as he is of any point of physiology, 4115–6; and contends that its action is so well known that further experiments are not needed, 4199.

Bernard's opinion.

Considers that it is sufficient to bring forward Bernard's opinion that curari is not an anæsthetic, without referring to other scientific men who differ from him, 4172–4.

Bernard although the introducer of curari deprecates its present excessive use, 4239–40; and expresses himself as if it were "horrible beyond all conception" to be under its influence; puts in the book containing the passage referred to, 4117–8.

Not considered an anæsthetic abroad.

In the laboratory in which Paul Bert's experiment was performed, has frequently heard it remarked, "Look at that animal, you would suppose it does not feel, but it feels doubly," 4234–7. It is scarcely possible that any man in France can believe that curari is an anæsthetic, 4177.

Human experience of curari.

Refers to particulars of two instances of human beings who had been put under curari, and of one who had been operated on under it; the latter complaining of "*douleurs atroces*," and the former speaking of the loss of power to move, while preserving entire consciousness, 4119.

Quotes Vulpian.

Quotes Professor Vulpian's statement, that "curari does not act on the sensory nerves, or at least does not abolish their function;" it "in no way annuls sensation, at least in ordinary doses," 4126–9; whilst in larger doses it destroys not only the power of the sensory nerves, but life itself, 4175–83.

Refers to Yule's experiments.

Thinks Mr. Yule's experiments with curari on a frog, assuming him to be correctly described in "*Nature*," must be disregarded, as the results obtained are opposed to those arrived at by the greatest authorities in experiments which he has himself seen, and considers the arguments based on them are invalid, gives details, 4121–31.

Limits of Experiment.—Advocates the regulation, but not the abolition of vivisection, 3435–7; wishes to stop abuses, but not to hamper investigation, 4065.

Repetition of experiment.

Considers the repetition of painful experiments demonstrating admitted results an abuse, gives instance of an experiment of this kind, 3454–8; but does not approve of limiting painful experiments to investigations with regard to new discoveries, as it would be a useless restriction and be easily evaded, 4244.

Demonstration on living animals unnecessary.

Does not consider demonstration on living animals necessary, mechanical contrivances, such as the sphygmograph, will show all that is necessary, 4244; thinks class demonstration on living animals should be forbidden under heavy penalties, 4244.

Vivisection should only be allowed in a theatre open to the public.

Regulation of Experiment.—Has discussed the question with numerous other persons, and they agree in considering, 3442–52, 4083, 4088, 4100; that private vivisection should be forbidden under penalties of imprisonment, and that experiments on live animals should only be allowed in places fitted with proper appliances, and containing a gallery to which a small number of the public should be admitted by ticket; gives details, and points out various advantages arising from such a course, 3438–41, 4084–7.

Experiments on certain animals should be forbidden.

Such institutions should also contain accommodation for animals on whom pathæological experiments were being tried; the use of anæsthetics should be compulsory, and that of curari forbidden in the operations, and such animals as horses, monkeys, dogs, and cats, exempted from experiment, 3441.

Does not think that the animals being used for pathological experiments would be disturbed by being seen by the public, who should not be able to touch them, 4096–9.

Public spectators.

Thinks five or ten students and a like number of the general public, who should be admitted in the same way as they are to the British Museum reading room, 4067–9, should be allowed to go into the gallery. Admits that the public would not be competent to appraise the scientific value of experiments, but thinks the plan would prevent misrepresentation as to the objects and nature of experiments, 4070–3; although the public spectators might, for instance, mistake reflex movements for signs of pain, just as they might not be aware of intense suffering when there was no movement, 4091.

Admits that the spectators might resort to manifestations of repugnance or disapproval; but thinks that under proper regulations such proceedings could not be repeated, 4092–5; and points out that the scheme proposes that complaints may be made to the superintendent, 4092.

Admits that vivisectors would object to be over-looked, but the prevention of carelessness and cruelty would outweigh this disadvantage, 4074–8; would advocate the same course in regard to operating theatres, if it should appear that in England the instruction of students was placed before the feelings of the patients, 4079–81.

"Cruelty to Animals" Act.

Does not desire to see any alteration in the Cruelty to Animals Act, 3441; and does not advocate licensing persons, 4082.

EMANUEL KLEIN, M.D.

Assistant professor at the laboratory of the Brown Institution, Lecturer on histology at St. Bartholomew's Hospital, and author of part of the Handbook for the Physiological Laboratory, 3528–30, 3620.

Studied pathology and histology at Vienna under Prof. Brücke and Prof. Stricker for four years, 3690–4, 3737; has subsequently practised in Vienna, 3545, and in London, 3556–7; and is now attached to the Brown Institution, 3688; has tried very few physiological experiments in England, 3610, 3594, 3596; the most painful experiment with the knife in his special researches has been injecting into the jugular vein, 3686–7, 3652–3; his experience of vivisection has been principally abroad, 3582; performs no experiments in his lectures at St. Bartholomew's, 3558–9.

Experiments for demonstration.

The Brown Institution.—Has, with Dr. Sanderson, the direction of those that come to the Brown Institution to make special researches, 3620, 3572; and performs certain experiments in his private room for teaching purposes, 3612, before students who come from the hospitals in order to go more thoroughly into microscopic or histological anatomy, 3626.

Anæsthetics.

There is no class, 3663, but experiments are performed it may be for one student only, 3675; there are in all three or four painful experiments, principally on frogs, which are killed as soon as possible—gives details, 3664–70; considers, however, that the frog's sensibility is of a low order, 3583–9, 3707–16; anæsthetics are only used for convenience' sake, 3631–3; and the frogs are not pithed, 3681–3; about 10 or 12 animals, mostly frogs, no dogs, and possibly one kitten, are consumed during the year, 3676–80; has performed these experiments for about three years, 3665; the animals are obtained by private purchase, 3575–8.

Witness' position with regard to the University of London is not clearly defined, but he has received a title and works in the laboratory, and lives in the Brown Institution, but receives no remuneration, 3574, 3612, 3615–7.

Nature of the investigations for Government.

Investigations made for the Government.—The experiments made at the request of the medical officer of the Privy Council, 3621–5, 3649–51, have been very few, 3609; and have all been of a pathological nature, 3611; and have related to tuberculosis, typhoid fever, sheep-pox, and pyœmia, 3581; the only operation involved has been making an incision for the purpose of making an injection, 3590–3, 3595, 3652–3, 3662; no anæsthetic was given to the dogs because of the pain being small, but the cats were chloroformed for the sake of convenience, 3597–8, 3636–43; some of the diseases induced, 3630, 3634–40, have been painful, but chloroform could not be used, 3656–9; monkeys, dogs, cats, frogs, and other animals, bought at the Government expense for the purpose, have been used, 3590–3, 3684–5, 3576–7; the total number used during 1874 was 14 or 15, 3614;

Mr. Forster's Minute.

Mr. Forster's minute did not apply to these experiments as there were no severe operations, 3645–8, 3746–9; with the exception of these experiments witness has performed no private experiments, 3579–80, 3607–8.

Use in demonstrations.

Anæsthetics.—Never uses anæsthetics for the lower animals, but thinks that in experiments on the higher animals for demonstration they should be used out of deference to the feelings of those present, 3538, 3542, 3563; cannot say whether their use affects the efficiency of the demonstration, 3555.

Klein, Emanuel, M.D.

Use for convenience' sake.

In investigation anæsthetics should not be used, 3562–3, except for convenience' sake, 3660–1, 3538; gives instances, 3599, 3562, 3602–5; an investigator has no time to consider the sufferings of the animal, 3538–44, 3542–4.

Dogs.

Some experiments,—gives instances,—can be done in less time and with less suffering to the animal without chloroform than with, 3560–1, 3741–5; giving chloroform to dogs is a long and probably painful operation, 3601, 3654–5.

Disregard of animal suffering abroad.

In painful experiments when chloroform cannot be used witness asks whether any of the students object, 3550–2, 3627–8; on one occasion the experiment on the cornea of a frog was objected to as being useless, and was not performed, 3671–5; believes on the continent the feelings of the animals are entirely disregarded, 3546, except when interfering with the convenience of the operator, scientific men being of opinion that animal suffering is of little importance compared with scientific research, and the general public abroad not claiming to criticize scientific matters, 3549, but the English public appears to have a considerable regard for the feelings of the animals, 3547–8, 3554; believes, but cannot say definitively, that investigators in pure physiology, 3700–6, share his views with regard to anæsthetics, 3606, and thinks there is little difference of opinion between English and foreign physiologists on the point, 3553, but admits that Dr. Sanderson does not agree with him, 3750–2.

Considers curari an anæsthetic.

Curari.—Considers curari an anæsthetic, 3718–20, because it stops breathing and therefore diminishes the vitality, and also because Dr. Schiff's experiments at Florence—gives details—appear to prove that it acts on the sensory nerves. Is unaware of Claude Bernard's reasons for holding the reverse opinion, and also of the experiments on two human beings, 3753–74; its action on the respiratory organs prevents its use in some instances, 3600.

Use of anæsthetics taken for granted when possible.

Handbook for the Physiological Laboratory.—The book is intended as a guide to students working under proper rules and competent supervision, 3533, 3537, 3565; it is assumed that anæsthetics will be used whenever possible; considers that this rule is accepted in English laboratories, 3566–7; has performed the experiment on the mesentery of the frog about twice for teaching and several times for pathological purposes, 2723, under curari, which witness considers an anæsthetic, 3719–26; has not performed experiments on the injecting small mammalian animals, 3727–8, nor on arterial pressure in England, 2729.

In England.

Extent of Practice of Vivisection.—Physiology is much more attentively studied in England now than when witness first came over, 3567–70; does not think there is any private experimentation out of a laboratory, 3571.

Abroad.

Prof. Stricker's laboratory at Vienna is intermediate in point of size between Prof. Brucke's and Prof. Ludwig's, 3734–8; there are no lectures given there, 3693, but the amount of work done is very great, and the number of animals used, principally frogs, dogs, and rabbits, very considerable, 3695–9, 3730–3.

EDWARD ALBERT SCHÄFER, M.R.C.S.

Assistant Professor of Physiology at University College, London, 3765–6.

Was educated in England, but has studied abroad, 3793. Has been a lecturer for two years at University College, and studied there for eight years previously, 3803–4. Witness' teaching is entirely on the tissues, 3775.

Believes that both professors and students desire to minimize pain, 3772–3; and that from feelings of humanity, anæsthetics are given whenever possible, and that almost all experiments are under them, 3770–1, 3779, 3807–9; very few painful experiments are performed, 3774.

In the practical physiology section there are two divisions; one for demonstration on the living animal, and another, of recent origin, in which advanced students, or medical men, perform experiments in conjunction with the professors, 3778.

A large number of frogs, about half a dozen dogs, and a somewhat larger number of rabbits are consumed in the year, 3782–3.

Frogs.—At University College, during the last 10 years at least, 3805–6, anæsthetics have been seldom given to frogs, 3788–90; either for research or demonstration, 3809–10, 3866–7; they are, however, often otherwise made insensible, 3837, 3865; with the view of facilitating the experiment, rather than from consideration for the feelings of the frog, 3798–800, 3864. Many of the experiments, however, are very severe, and would be very painful if the frog had proportionate sensibility, 3795–6, 3801.

Schäfer, Edward Albert, M.R.C.S.

Thinks chloroform would be a great irritant to the skin of a frog, 3816; and has doubts whether the anæsthetic would not cause as much pain as the operation, 3797.

Does not consider the frog as sensitive as the higher animals, 3791; besides it cannot reason about its sensations, 3859. Thinks a frog's restlessness when irritated by a parasite due in part to reflex action, 3860–3.

German frogs are preferable to English, because the parts are larger, 3784–7.

Extent of practice of Experiment.—The number of laboratories in London is very small; the largest are attached to University College, Guy's Hospital, King's College, and the Brown Institution, the number of workers in them could be easily arrived at, 3820–3. Is unaware of the existence of any private laboratories, 3817–9. Does not believe in the existence of any private experimentation by students, 3824–7.

Experimentation Abroad.—Was at Professor Ludwig's laboratory for three months during the past summer, 3850–1; the annual consumption of animals there would amount to more than 100 dogs and rabbits, besides frogs, 3852–5. Foreign physiologists endeavour to minimize pain, 3856–7. There are not many painful demonstrative experiments abroad, but more than in England, 3858.

Experiments for Demonstration.—Has seen formidable, but not "frightful," experiments performed before students, but always under anæsthesia, 3828–32, 3836. A painful experiment without anæsthetics before a class would be likely to cause a commotion among the students, 3833–5.

Experiments should only be repeated when there is doubt as to the result, 3813; results arrived at by such men as Professor Ludwig would be at once accepted in England without repetition, 3814–5; experiments in his own research have been entirely novel, 3812.

Curari.—Is doubtful as to how far curari is an anæsthetic, and therefore, when possible, frequently gives opium as well, 3780–1; instances experiments in which opium is also given, 3838–45, 3848–9.

JOHN GRAY M'KENDRICK, M.D.

Lecturer on Physiology at the Extra-Academical School of Edinburgh, 3869–72; and at the Edinburgh Royal Veterinary College, 3876.

Is also in private practice in Edinburgh, 3868; and was formerly also assistant to the Professor of Institutes of Medicine in the University, 3873, 3875; has been connected with the Veterinary College for a year, no experiments on live animals are performed there, 3970–3; the lectures at the school qualify for graduation at the university, 3872.

Necessity for Experiment.—Thinks that little additional knowledge with regard to the nature and origin of disease is to be hoped for from anatomy, or from the old methods as to the action of drugs; thinks further results must be gained by experimental methods, 3987–92; for instance, although anatomy did something in tracing the nerve fibres of the spinal cord it was reserved for physiology to show that the fibres on each side were connected with the opposite side of the brain, 3878–9.

Considers that a correct diagnosis of many diseases would be impossible without the knowledge obtained by the experiments of Bell and Brown-Séquard, 3878; and points out that the more we know of the nature and origin of disease the more possible prevention and cure become, 3992–4.

Probable decrease of vivisection.

Believes that as science advances vivisection may become less necessary; instances the investigation into the changes produced by light on the retina, in which it was thought necessary at first to excise the eye for experiment, but the facts can now be demonstrated all but painlessly on the live animal, 3905–6.

Increased knowledge.

Results obtained by Vivisection.—Reads portion of an article contributed to the British Medical Journal by himself, entitled "What has Vivisection done for Humanity?" Contends therein, i. *That it has advanced* *physiological knowledge;* instances 22 discoveries with regard to the functions of the nerves and nerve centres, the physiology of the circulatory, respiratory, and digestive organs, the action of light on the retina, and the phenomena included under electro-physiology. ii. *That it has aided medicine and surgery;* refers to the transfusion of blood, artificial respiration, knowledge of the causes of the sounds of the heart, the cure of aneurism, the knowledge of the phenomena of inflammation, and of the nature of zymotic diseases as supporting this view. iii. *That it has advanced therapeutics,* by the discovery of anæsthetics, of the action of many drugs, and of antidotes, 3916, 3878. The article enumerates the more important advantages obtained only, 3917–21.

Improved treatment.

Refers to the abandonment of the section of seventh nerve for neuralgia, 3879; and also, in some detail, to Dr. John Reid's experiments on the cranial nerves; to witness' own, in conjunction with Dr. Dewar, on the effects of light on the retina; Dr. Hope's on the sounds of the heart, and those by Dr. Hughes Bennett and others with regard to the antagonism of certain drugs and the discovery of antidotes or probable antidotes for strychnia and the Calabar bean, 3879.

Antidotes for strychnia and Calabar bean.

Points out that accurate knowledge of the action of most drugs has been reached by experiment, 3921; and that scientific results often produce practical, though unforeseen, benefits, 3795.

Chinoline.

Refers to his investigations, in conjunction with Dr. Dewar, resulting in the discovery of the anæsthetic effects of chinoline, which has the remarkable effects of acting on the nerve centres rather than on the nerve terminations, and of not interfering to any great extent with respiration; refers to experiments with it, 3906–14; this discovery was made in 1874, and has awakened much interest, but as it produces nausea in the human being is of little practical value at present, except for the lower animals; further investigation is needed with regard to its power and capabilities, 3922–8.

Sir James Simpson.

Believes Sir James Simpson experimented on animals with chloroform and many other substances, but he also tried them on himself and his assistants and was often ill after his experiments, 3945–2.

Cannot recollect details of Dr. Hughes Bennett's experiments with mercury on the liver of dogs, 4001–2.

Does not experiment on frogs as if they had no sensibility, but kills them first, 3915.

Had relief of pain and cure of disease in view in most of his physiological experiments, those on the eye were for purely scientific ends, 3972. The infliction of pain is an evil justifiable only when a great advantage is obtainable, 3895–6.

Believes that the progress of discovery is likely to be rapid, judging from the results of recent years, 3930. Discoveries are always promptly announced to the profession, 3984. Thinks the advance of physiological science will tend to mitigate the sufferings of animals, 4020–1.

Anæsthetics.—There is a considerable latitude of opinion among physiologists as to anæsthetics, 4009; considers that, except with regard to the action of drugs, nearly all experiments in original research may be rendered, either wholly, or in part, painless, 3899–905, 3933; thinks even if an anæsthetic affects the organ experimented on, an allowance may be made for its effect; points out that a severe operation introduces abnormal conditions, especially if pain be felt, and the physiologist often has to choose between the disturbance caused by pain and the disturbance caused by an anæsthetic, 3934–8.

Allowance for the effects of anæsthetics.

In experiments on the nerves,

Believes that some of the facts connected with the nervous system might possibly have been ascertained under partial, though not under complete, anæsthesia; the most painful experiments were, however, done so carefully, and are so well corroborated that they need not be repeated, 3941–4; anæsthetics were used in the experiments with regard to the effect of light on the retina; had the experiment failed it would have been tried once, with all possible precaution, without anæsthetics, 4015–6; considers these experiments his principal work, 3985–6.

and on the retina.

Effects on the liver.

Curari.—Believes that Dr. Rutherford first tried the effect of curari on the liver, and then when trying the action of other drugs on animals under the influence of curari made an allowance for its effects; cannot say whether it would have been possible to have used an anæsthetic and then made an allowance for it, 4003–8; in such experiments the pain, which in this instance would be severe, and the probable scientific gain should both be considered, 4017–8.

Experiments for Demonstration.—For demonstration only painless experiments are necessary, 3898, 3933; is content to show students the physiology of the nerves, muscles, and heart, and certain facts regarding respiration on decapitated frogs, 3897; but does not think it necessary to show students the action of strychnine, or the action of hydrate of chloral as an antidote, except in the case of advanced students, 3886–92, 3966–9; the experiment, moreover, is not very painful and is soon over, 3880–5.

Painless experiments only needed.

Action of poisons.

Experiments by Students.—Except under the superintendence of the lecturer, students are not encouraged to attempt private experiments at Edinburgh, which is probably the most active school in the kingdom, 3893–4, 3996–9.

In one instance, witness heard of a student experimenting on a cat, but having pointed out to him the useless nature of his proceedings they were abandoned, 3915; as a rule, neither students nor young medical men practice experimentation, 3974–9, except under supervision or when preparing their theses, 3979–81; very few experiments can be performed out of a laboratory, the appliances now used are very expensive, 3982–3.

On a cat.

Regulation of Vivisection.—Does not see how legislation can regulate vivisection, 3953–4; and fears it would retard the advancement of science, 4012; has a private laboratory himself, 3960–5; and disapproves of licensing places as likely to inconvenience competent and earnest men, but does not object to licensing persons, 3955–8, 4012, 4019.

Licence system.

Persons who avow that the sufferings of animals are beneath the concern of the physiologist should be restrained; is entirely of an opposite opinion, 3959.

Considers that experimenters should either be competent physiologists or under one, 4010; but would rather dissuade them from the practice than restrain them by law, 4011.

If there were great abuse of the practice of experiment would approve of adequate restriction even at the risk of retarding the advancement of the science, but does no believe such abuse exists, or is likely to exist, 4013–4.

MR. ROBERT SAWYER.

Is a member of the legal profession, and of the Committee of the Society for the Prevention of Cruelty to Animals, 4246–7; also of the society's sub-committee on vivisection, but does not think he concurred in the report referring to the "grim" character of Dr. Ferrier's experiments, 4278–81.

Heard the whole of one of Dr. Ferrier's lectures at the London Institution, and considered it very interesting, 4249–52, 4270. From 50 to 70 persons were present, 4264–5; Mr. Colam, Mr. Reid Thompson and Mr. Thomas Allen were also there, 4259, but not in the same part of the room, 4260–1.

Dr. Ferrier's lectures at the "London Institution."

Understood Dr. Ferrier to say that the animals were rendered insensible to pain, 4253–5, 4257–8. Thinks that the experiments on the brain of an insensible monkey went to show that exciting particular portions produced movements usually denotative of pain, 4267–9; did not understand that Dr. Ferrier had performed a single unnecessary experiment, and did not think that the lecturer covered the "grim character of the experiment by his humour," 4276; but he seemed to witness to consider that he was justified in taking the lives of any number of animals for his investigation, 4256, 4272.

Experiments on the brain of a monkey.

Was sorry to hear Dr. Ferrier's smiling remark, 4274–5, that he was "afraid to say how many cats he had" experimented on, received with a titter, 4253, 4266; believes the reference to the stupidity of the monkey must have occurred at the other lecture, at which he was not present, 4282–3.

JOSEPH LISTER, M.B., F.R.S.

Professor of Clinical Surgery in the University of Edinburgh, surgeon in ordinary to the Queen in Scotland, 4284–5.

Results obtained by Experiment.—Refers to the advantage he has derived from his first experiments, 4338, made when he was first appointed a teacher, 4303–6. These experiments eventually led to the development of the antiseptic system of treatment which was tested in the first instance on calves and horses, 4350–8; considers that these experiments caused very little pain after the operation, as a properly applied ligature causes little or no pain even in the human being, 4359–62.

Discovery of the antiseptic method of treatment.

Considers that experiments on living animals is one of the most important means of increasing knowledge, 4291–2.

Experiments for Demonstration.—Attaches very great importance to demonstration as a means of instruction, 4339–43, gives instances of its advantages, 4312–3; has only employed it on one occasion himself, many years ago, as his subject, practical surgery, does not from its nature require it, 4308–9, 4317–23.

Anæsthetics should always be used.

Considers that in class demonstration anæsthetics should be used, not so much because it saves the animals pain, but because it prevents the demoralizing effects of seeing unnecessary pain inflicted, 4328; has never seen or heard of any levity at demonstration before classes, 4311, 4314, and does not believe that properly conducted experiments demoralize students, 4367–9.

Experiments should be performed for definite objects only.

Limits of Experiment.—Considers that in these experiments the prospect of a probable gain to the human race should over-balance personal reluctance to undertake them, 4329; but experimenters should always have a clear and definite object in view, 4328, and regard it as a duty to give chloroform in severe experiments whenever possible, 4321–2; is of opinion that in the higher animals experiments can nearly always be rendered either wholly or partly free from pain, 4293–4; and although thinking that painful experiments will be necessary, believes the pain will be usually short, 4296–7, 4315–6.

Effects of rhubarb on the secretion of bile.

Placing a frog in hot water.

Thinks the eight or nine hours suffering entailed on the dog while experiment was being made as to the effect of rhubarb on its liver justifiable, it would not suffer as much as a rat caught in a gin, 4404–7; placing the frog in water and raising the temperature would be painful, but does not consider the sufferings of the frog worth serious consideration, 4420.

Difficulty of giving frogs chloroform.

Anæsthetics.—The inflammatory action of chloroform on a frog's skin renders it inconvenient to use, 4379, 4416; believes that ether would be open to the same objection, and that even taking the frog in the hot hand would be very painful, 4417–19. It is a laborious process to chloroform a horse, and hardly necessary except for severe operations, 4331–7.

Sensibility of Animals.—Entertains no doubt that the lower the organization, the lower the sensibility, gives various reasons and examples, 4374–8. Cannot compare the sensibility of a rabbit and a dog or guinea-pig, or of a wild fox and dog, 4432–4.

The frog "the physiologist's animal."

Does not think the frog capable of suffering much pain, gives reasons, 4390, 4411–4; considers that it has become "the physiologist's animal" on account of its tolerance of severe treatment, and from the fact of its comparative insensibility, 4391; and does not consider it necessary to give them anæsthetics, 4415; believes that it would be very difficult to prove that frogs *suffer* from parasites, 4392; points out that the kicking and struggling of a frog or of a worm on a hook goes on after the brain is removed, and cannot therefore be an evidence of pain, 4380–1, 4384–5, any more than the unconscious movement of a paralysed limb or of the sensitive plant, 4386–9.

Convulsive movement not necessarily a sign of pain.

Vivisection and pheasant shooting.

Non-scientific vivisection.

Believes that the pain caused by vivisection in Great Britain during a whole year would be exceeded by the amount produced in a single day's pheasant shooting, 4328, 4401; and points out that popular feeling acquiesces in the removal of a blemish from a horse, 4408–10; and in the castration of animals for human comfort and convenience, and contends that operations for scientific ends stand on far higher ground, 4328.

Humanity of English vivisectors.

Believes experiments in England are only undertaken by competent men, 4426, and that there is no danger of inhuman vivisection here, 4401–3. Considers that medical men are the most humane class in the community, they know more accurately what suffering is, 4330, and see more of it, 4395; admits, however, that this does not apply to the increasing class of pure physiologists, 4396–8; contends also that the inevitable pain inflicted before the discovery of chloroform by operations, did not render surgeons hard-hearted, some, such as Mr. Syme, were among the kindest of men, 4370–1.

Mr. Syme.

Difficulty of defining competency.

Regulation of Experimentation.—Admits that painful experiments should, in the interests of science, be undertaken only by most competent persons, 4297*a*–8; but points out the difficulty of saying who are competent, 4301; and doubts whether legislation would not retard research, 4299–300; would himself consider a thoroughly instructed medical student "competent," 4303; believes men unknown to fame undertake such experiments, and thinks it would be as undesirable to check them as it would have been to have stopped Davy's and Faraday's experiments when they were unknown, 4324–7; has never known of any experiments by incompetent persons, 4302; thinks it would be undesirable to exempt the domestic animals from experiment, 4421–4.

Exemption of domestic animals from experiment.

Objects to limiting experiment to public laboratories, and considers that admitting an uninstructed public to see experiments would be most undesirable, gives reasons, 4348–9.

Does not think that nine-tenths of the original research going on could be stopped without loss, but if it could, no one can say which tenth should be retained, 4399–400.

Legislation would be a slur on the profession.

Thinks prescribing by law that experiments for demonstration should only be allowed under anæsthetics unnecessary, and considers that it would be a slur on the profession, 4344–7, 4393, it would imply a fault where none exists, 4430; does not think the case of the Factory Acts analogous, 4394.

Objects to legislation as being superfluous, 4425–9, although admitting that if it did not interfere with private investigation it would not be objectionable, 4431.

Analogy between man and other animals.

Miscellaneous.—Considers that as the phænomena presented by horses and calves is similar to those observed under similar circumstances in the human being, it is reasonable to suppose that the results will be analogous, 4363–6; has not attended lectures or experiments by others since he was a student, 4310, and has conducted all his investigations in private, 4307.

Mr. Syme's experiments were very important, and though before the discovery anæsthetics were performed as humanely as possible, 4286–90.

MR. GEORGE RICHARD JESSE.

Honorary Secretary of the Society for the Abolition of Vivisection, 4437, and formerly a railway engineer, 4436.

States that the society regrets that a Royal Commission has been considered necessary, and is of opinion that what is needed is the enforcement of the Cruelty to Animals Act, 5556; regrets the supineness of the Society for the Prevention of Cruelty to Animals, and deprecates any legislation short of forbidding vivisection, 6475; the society's object is to show the demoralizing effects upon the experimenters themselves, especially as boys and girls are now to be taught physiology, *page* 271. Believes that Professor Huxley's "Elementary Physiology for Boys and Girls" is an evidence of the spread of vivisection, and shows that in place of mercy, cruelty, "the most devilish" of vices, is being taught instead, 6465–7; objects to enter into technical questions, but decidedly considers that the passage quoted (*see* 6511,) from that work is a distinct encouragement to vivisection by young students, 6506–23, and that the other passages quoted have some tendency in the same direction, 6524–7.

Juvenile vivisection.

Is prepared to establish that the cruelties of vivisectors are not surpassed by any recorded in the history of mankind, 4439; considers vivisection itself a moral ulcer, and proposes to read extracts from various works to prove it, 4438–9; protests vehemently against it, giving various reasons and arguing that it tends to divorce intellect from moral principle, 6475.

Discusses various reasons advanced in support of vivisection, and rejects them all, considers that it entails degradation of mind as proved by the examples of Spalanzani, Brachet, &c.; quotes various writers in supporting this view, 6475; and observes that the society has abstained as much as possible from referring to continental practice, 6473.

Human vivisection.

Believes it not impossible that physiologists would vivisect human beings if they dared—criminals were vivisected at Montpellier, baby farms in England have not escaped suspicion, whilst in America a poor and friendless woman was actually made the subject of experiment, 6475.

Insignificance of the discoveries made by vivisection.

Discoveries wrongly ascribed to vivisection.

Maintains that the discoveries made by this means are utterly inadequate to justify such cruelty. Begs that the Commission will ask each vivisector to specify his individual discoveries by this means, and then obtain the opinion of impartial men with regard to these alleged discoveries, 6475; points out that Harvey's, Hunter's, and Bell's great discoveries were not made, as is too often erroneously supposed, by vivisection, and that high medical authorities, such as Gall, Curwin, Bell, &c., have said that vivisection is not only useless but misleading, 6475.

Hospital funds.

Witness admits that he was unaware that the funds of the hospital as a charity are entirely distinct from those of the medical school, but contends that the prospectuses of the hospitals seem to him to favour the view, 6528–49, that the money given to cure the sick is misappropriated for torturing animals, 6475.

States that thousands of letters have been received by the society from educated persons urging in strong terms the abolition of vivisection, and contends that such deep feeling could not have arisen without sufficient cause, 6475.

Complains of the "unfair conduct" of certain newspapers in the matter, 4439.

Was not aware, but is glad to know that the Council of the College of Surgeons in London expressly states that vivisection is not required, 6550–1.

Dr. Hughes Bennett's experiments on a cat.

Reads a variety of extracts to prove the correctness of the views held by the society, commencing with a detailed account of Dr. Hughes Bennett's experiment in which theine was injected under the skin of a cat, the results being intense cerebral excitement, gradual loss of power in the spinal chord, and death, 4443.

Dr. Ferrier's experiments.

Alleges insufficient use of anæsthetics.

Reads papers referring to Dr. Ferrier's experiments giving details of experiment on a guinea-pig which was narcotized, experimented on, allowed to recover from stupor, and then again narcotized, *page* 220; adverts to Dr. Ferrier's observation that "before and throughout "all the following experiments ether or chloroform was "administered," and infers that the experiments preceding this remark on guinea-pigs, rabbits, and cats, were not under anæsthesia, *page* 230; also draws attention to the expressions "the animal was only partially narcotized," "with and without chloroform," &c., *page* 220; refers to an experiment on a rabbit in which, during the five days intervening between the first and second operations, the exposed part of the brain became *the* seat of suppuration and fungus cerebri, *page* 220.

Growth of fungus cerebri during an experiment.

Functions of different parts of cats' brains.

Reads in detail a series of observations made during an experiment lasting four hours on a strong cat in which the right hemisphere had been laid bare, referring to "signs of pain," "cries as if of pain or rage," "spitting," &c. under the action of electricity, *pages* 220–1.

Of dogs' brains.

Refers to various experiments on dogs and specially to one lasting eight hours, during which various portions of the brain were successively removed, and the various phenomena observed, some of which Dr. Ferrier considered apparently attributable to retention of consciousness, and a distinct sense of pain; amongst other things, "when called to it would struggle to get up," "it ran against furniture, walls, and jammed its head into impossible corners," *page* 221.

Correspondence with Dr. Ferrier.

Reads correspondence between Dr. Ferrier and himself, in which the former complains of not being fairly quoted, and also of the erroneous inferences drawn with regard to the use of anæsthetics, *pages* 221–3; reads, from the pamphlet in which this correspondence is published, remarks on the subject, *page* 222.

and Dr. Crichton Browne.

Reads letter which appeared in the "Times" from Dr. Crichton Browne, complaining of certain statements with regard to Professor Ferrier's researches which appeared in the advertisement of the Society for the Abolition of Vivisection, characterising it as "skilfully misleading," and the conclusions deduced from the "adroitly selected," quotations "as unwarrantable," also reads reply from himself which did not appear in the "Times," contending that the manifestations which usually imply pain, implied it in these instances, and that many of the expressions used in the descriptions indicate that this view is correct; also asserts that chloroform is given to narcotize the public mind, and make the patient helpless, *page* 221.

Partial consciousness of animals under experiment.

Read various extracts from the proceedings of the Royal Society relating to Dr. Ferrier's experiments, many parts of which are described in detail and desires to draw particular attention to the fact that in some of them the "animals were rendered only partially insensible during the process of exploration," that in others it is stated that the animals did not "apparently lose consciousness completely," and that in one instance the animal was allowed to remain quite conscious during stimulation, *pages* 275–7.

Reads passages from Hansard, giving details of experiments which excited great disgust and sensation when brought to the notice of the House of Commons, in order to prove that the cruelties of vivisection are not exaggerated, *page* 223.

Refers to Drummond's "Rights of Animals," and various passages in Dr. Wilson's "Life of Dr. John Reid," and reads passage referring to the remorse expressed by Dr. Reid for having inflicted such sufferings on animals, *page* 223.

Edinburgh University.

Reads particulars with regard to the recent plans for

a physiological laboratory at the Edinburgh University, *page* 223.

Quotes from the "Scotsman" a passage by Dr. Rutherford, referring to the practice at Edinburgh University of performing experiments without narcotics when necessary for the purpose of research or verification of results, *page* 223.

Huxley's Elementary Physiology.

Reads extracts from Professor Huxley's "Lessons in Elementary Physiology" for "boys' and girls' schools," describing various experiments on the spinal chord, sympathetic nerve, &c., and also quotes the preface to the effect that the organs and tissues of the common domestic animals afford sufficient material for acquiring a practical knowledge of elementary physiological anatomy, *pages* 223–4.

Alfort.

Refers to passages in various works relating to the subject, and among them one describing the horrors formerly perpetrated at Alfort, and another relating to experiments by students in their rooms; does not know the writers of these works or anything beyond their statements, 4446–55.

Dr. Chalmers.

Puts in a reference to a sermon by Dr. Chalmers against vivisection, 5553–6.

Majendie.

Quotes various passages from Dr. Elliotson's "Human Physiology," tending to show that Dr. Majendie was in the writer's opinion unnecessarily cruel, also others referring to the unsatisfactory nature of the experiments made by various eminent men, and to Gall's and Sir C. Bell's objections to vivisection, *page* 271.

Experiments on the brain of dogs.

Quotes from a work by the editor of the "Veterinarian" an account of experiments on birds, in which various portions of the brain were removed, and the phenomena presented under exposure to violent pain, to heat, to burning by red hot irons observed, also of experiments on dogs, in which a gimlet was forced into the brain of a dog and its doings observed for six days, and of another in which the experiments lasted 16 days, during which it retained in part its docility and intelligence, *pages* 271–2; and reads further extracts, one giving Sir Charles Bell's opinion against men causing protracted suffering, and another referring to mental and moral attributes of animals, *page* 272.

Sir Charles Bell.

Reads extracts from the "Quarterly Review," Mayhew's "Dogs, their Management," Blaine's "Canine Pathology," the Memoirs of Dr. Wilson of Edinburgh; the Life of Sir Astley Cooper, the last, witness contends, showing the demoralising effects of vivisection, *page* 272.

Dr. John Reid's experiments.

Reads passages from Dr. John Reid's Researches, to show the contradictory opinions of various eminent vivisectors as to the cause of death, and nature of asphyxia, *page* 273; quotes various passages from Dr. Reid's works, showing the painful nature of some of his experiments on the nerves, and giving full details in several instances; also refers to Dr. Reid having abandoned several experiments on account of their painful nature, *pages* 273–5.

Sir Walter Scott's opinion.

Quotes Sir Walter Scott to show the demoralising effect of vivisection on vivisectors themselves, reads passages from the "Personal Recollections of Mrs. Somerville," *page* 275.

Reads extract from his own "History of the British Dog," *page* 275.

Biliary fistula in cats.

Reads extracts from St. Bartholomew's Hospital Reports 1873, containing an account of Dr. Legg's experiments on biliary fistula in cats, and giving details with regard to some of the experiments, which lasted from 5 to 29 days, and also adverting to the differences of opinion existing with regard to the cause of death, *page* 277.

Effects of aloes and rhubarb on the liver.

In order to show that painful experiments are being carried on, reads extract from the British Medical Journal, giving details of experiments for testing the effects of aloes and rhubarb on the biliary secretion of the dog, *pages* 277–8.

Gives references to passages in numerous works to which he desires to direct the attention of the Commission, 5566.

Vivisection a source of error.

Sir Charles Bell's discoveries were not made by it.

Quotes Sir Charles Bell's opinion that vivisection has "never been the means of discovery," and "has done more to perpetuate error than to enforce just views," and that his own discoveries were deduced from anatomy not experiment, and stating that he only resorted to experiments because his utmost powers of persuasion were lost without them. Reads from Pichot's Life and Labours of Sir Charles Bell, an extract from one of his letters showing his reluctance to experiment on live animals, reads also the author's account of Sir Charles Bell's reasons for objecting to vivisection. Reads further passages with regard to the necessity of pain, and the littleness of man, and his greatest discoveries, and contends that they bear on the subject with which the Commission has to do, 6423-5; refers to Collier's Translation of Celsus with the same object, 6425-7.

Spalanzani.

Reads extract from Macilwain's "Memoirs of Abernethy," in which Abernethy censures Spalanzani for having "tortured animals in vain," and says that the nature of some of his experiments prove him to have been a "filthy minded fellow," 6436; reads other passages from the same work, 6436–40.

Mr. Erichsen's experiments with regard to asphyxia.

Reads extract from an article by Mr. Erichsen in the Edinburgh Medical and Surgical Journal of January 1845, on the pathology and treatment of asphyxia, giving details of an experiment (one out of several) in which the circulatory systems of three dogs were connected by tubes and one of the dogs suffocated, and the phenomena observed, 6453–8; was aware that the results of these experiments were reported to the British Association, but not that the Royal Humane Society had awarded Mr. Erichsen the Fothergillian gold medal for these researches, 6459; puts in reference to a passage with regard to vivisection in Bayle's Dictionary, 6459–6460*a*.

Private experimentation.

Refers to Baker's edition of Kirke's Handbook of Physiology as a book "calculated to make young men "try these so-called experiments in their lodgings or "elsewhere," 6460*a*, and as containing records of very cruel experiments, 6466–70.

Contrary opinions held by vivisectors.

Reads passages showing differences in the results arrived at by different vivisectors, and referring to the contradictory opinions held, 6460*a*, 6473; reads accounts of experiments showing the condition of the brain in various forms of death, 6460*a*, the intensity of the respiratory efforts when the animal is deprived of air, and the various phænomena observable during apnœa, 6465; the extremes of temperature which animals can endure, the phenomena attending starvation, the digestion of the stomach after death, the reproduction of the extremity of the tail after amputation in the salamander, also reads passages relating to the functions of the pneumo-gastric nerve, &c., 6473.

Tenders an extract from the "Sporting Magazine" of 1825, and regrets that the Commission will not receive it as evidence, 6427–36.

Witness desires to read passages showing Mr. Macilwain's and Sir W. Fergusson's opinions, but is informed that the reading of those passages may be dispensed with as both those gentlemen have appeared as witnesses, 6438–43.

Inquires whether the Commission could supply the society with Dr. Ferrier's Croonian lecture, but is informed that the office of the Commission is simply to receive information, 6443–53.

Contends that the Commission having power to "call for, have access to, and examine" all documents giving "information on the subject," have power to receive letters addressed to the society, and regrets that they have decided not to do so, 5551–2, 5556–61.

Refuses to give particulars with regard to the society.

Can give a list of the members of the society with the exception of some who do not wish their names known, 4440–2.

Has made these statements on behalf of the society, but declines to state whether they were adopted at any meeting of the society, or whether there has been any general meeting, declines to state in what manner the committee was appointed, or whether there is a treasurer, or whether the accounts have been audited; considers such questions inquisitorial, and that the constitution of the society is a private matter with which the public has nothing to do; states, however, that the society was formed during 1875, that there had been a meeting of some of the members of the committee (but will not say of how many), and that the names of the committee had been advertised in the papers, 6478–6502.

ROBERT McDONNELL, M.D., F.R.S.

Examiner at the College of Surgeons, surgeon to Steeven's Hospital in Dublin, and formerly for many years Lecturer on Anatomy and Physiology, 4456–9, 4499–51.

Irish feeling on the subject.

Popular opinion on the subject of vivisection is very strong in Dublin, although no abuses exist in the Irish schools, 4460–1, calling for legislation, 4522; sentiments of humanity are strong both in the medical profession and among the students at Dublin, 4462–3; and also among both English and American physiologists generally, 4519–21.

Anæsthetics.—Both for demonstration and for original research anæsthetics can nearly always be employed, at any rate during the most painful portion of the experiment, 4466–9, 4585–6; always uses them himself when possible, 4518; they cannot, however, be used in experiments with regard to the nerves of sensation,—gives instances, 4486–8; but these experiments are very few in number, 4470–1, 4587; renders frogs and even tadpoles speedily insensible by putting them into water containing a little chloroform, 4563–5.

Anæsthetising frogs.

Necessity of experiment, including some painful ones.

Experiments for Demonstration.—Contends that certain experiments are essential in medical education; instances the exhibition of the circulation of the blood in a frog's foot, 4505–8, and Weber's experiment on the pneumogastric nerve, which can be done painlessly but cannot be adequately described in words, 4528; with very few exceptions does not approve of painful experiments before classes, 4568.

Improved method of surgical treatment.

Chloroform.

Artificial epilepsy.

Results of Experimentation.—Contends that the difference between the surgery of the present day and the horrible practices described by Ambrose Paré is largely due to vivisection, and urges that if the experimental method had been introduced sooner a hundred years of torture might have been saved. The discovery of chloroform, 4537–8, and of the present method of treating aneurism were arrived at by experiment, 4539–40; as also Dr. Brown-Séquard's peculiarly valuable discoveries with regard to the conducting channels of the spinal cord and the artificial production of epilepsy, 4491–8; refers in detail to the benefits resulting from the knowledge of the practicability of the transfusion of blood, and of the torsion, in lieu of the ligature, of arteries as examples of the advantages obtained by experiments on animals, 4541–62*a*; and observes that he believes so strongly in the benefits to be got by experiments, that in common with other medical men he has himself submitted to considerable pain in experiments on himself, 4575.

Experiments on himself.

Experiments by Students.—Never knew of any experiments by students; believes they would not tolerate an experiment without anæsthetics except for some good reason, 4464–5, 4512–3; if students attempt any painful ones they should be stopped, but they should be allowed under supervision to watch the circulation of the blood or the effect of a grain of mustard seed on a frog's foot, 4572–3; and those who desire to advance science should begin as soon as they have passed their final examination to experiment independently in the laboratory; did so himself, and has also made a very few experiments at his own house, 4514–7.

Experimental research has been long and humanely pursued in Ireland, 4511; but there is no practical course in any of the schools; has sometimes permitted some of his more intelligent students to be present at some of his private experiments, 4484–5, 4502–4; the total number of animals witness has used has been very small, 4509–10; considers that if a class is impressed with the idea that good will result from the experiment the effect is humanizing, whilst passively witnessing suffering would be brutalizing, 4480–3; the method of giving scientific instruction is much better now than 20 years ago; then even chemistry was not taught practically, 4524-6.

Difficulty of legislation and of inspection.

Regulation of Vivisection.—Believes that the position of physiologists would be improved by legislation on the subject,—gives reasons, 4476, 4479, 4490, 4523, 4588; but thinks the matter surrounded with difficulties, 4475; neither of the bills of last year appears to very well meet the case, 4477; a system of inspection could hardly combine the two essentials of being really efficient and of not interfering with the progress of science, 4478, 4589; the importance of an experiment is a matter of opinion, and often no one can foresee the result. Dumas could not have dreamt that he was on the eve of discovering such a blessing to mankind as chloroform when he was distilling ants to get formic acid; nor Galvani the electric telegraph when observing that electricity made a frog's leg move, 4575–8, 4580; the suggested admission of the public to laboratories would be useless, for physiologists would then experiment in private, and many delicate experiments would be rendered impossible, 4530, besides many movements,—gives instances,—really due to reflex action would be ascribed by the uninstructed to the presence of pain; recollects being once assailed for showing the pulsation of a frog's heart after its removal from the body, 4531–4.

Experiments in public.

Repetition of Experiments.—When a fact has been once thoroughly established the experiments demonstrating it if painful should not be repeated, although while the matter is *sub judice* they may be rightly undertaken, 4472–3, 4587; believes Brown-Séquard's experiment, which witness has himself performed, in which epilepsy is artificially produced, is painless,—gives reasons, 4571.

Duration of painful experiments.

Miscellaneous.—Classifies experiments, and states that setting aside experiments as to the action of drugs and a few others, 4490, protracted agony is never necessary, 4474, 4488, 4587. Cannot state the longest period which it is necessary to keep an animal in a state of pain, but the amount of suffering is often small and the time always brief, 4489, 4570.

Qualification necessary for discovery.

Disputes the assertion that nine tenths of these experiments are made by men incompetent to discover anything, 4579–84; the converse would be more accurate, 4581–3; what is required is painstaking carefulness and an exact record of facts; believes the discovery of galvanism, for instance, was really made by Galvani's wife rather than by the philosopher himself, 4575, 4580.

T. HAYDEN, M.D.

Professor of Anatomy and Physiology in the Roman Catholic University of Ireland, and Fellow of the College of Physicians, 4591–5.

Experiments for educational purposes;

Considers that experiments for demonstration are as a rule unnecessary and of little use except perhaps to senior students, 4598–9, 4603; when witness first became professor he performed some experiments,—gives details,—before his class to satisfy himself, but has performed none since. The higher animals used were always anæsthetized, 4595–7, 4600; considers experiments necessary in new ground even if painful,—gives instances, 4601–2. The feeling among educated Irish people is very strong on the subject of animal suffering, 4604–5.

for research.

MR. JOHN CLELAND, M.D.

Professor of Anatomy and Physiology at Galway since 1863, 4607–8, 4633–4, and formerly demonstrator at the great Anatomical School of Edinburgh, 4645–6.

Cruelty to Animals Act.

Regulation of Vivisection.—Has not seen the proposals made on the subject, but thinks the Cruelty to Animals Act, which might be widened to include all mammals, 4621–5, sufficient without further legislation, 4620; qualified teachers should be unrestrained as regards their choice of experiments, 4618–9, and as to the use of anæsthetics, 4611, on which point all physiologists must judge for themselves; believes, however, there would be less pain given if physiology were as well studied here as abroad, 1660.

Anæsthetics.—Ought to be used whenever possible in painful experiments on mammals, 4611–3, 4617, 4643, 4647–8; part, if not the whole, of an experiment can generally be done under anæsthetics,—gives instances, 4644; witness always piths or decapitates frogs instead of giving chloroform, 4632, 4658–9.

Frogs.

Sensation of Pain.—The extent of a frog's sensibility to pain is a matter of speculation, 4614–6, but from the low organization of its brain and other reasons,—given in detail,—considers that probably frogs feel no pain comparable to that felt by the higher animals, 4626–32.

Medical Education.—Is of opinion that the curriculum of medical education is very heavily weighted, 4640; and that students have not time for the experimentation necessary for thoroughly studying physiology, nor has a professor, who has two such subjects as anatomy and physiology, time to devote to it; in fact his own teaching produces medical men, but not physiologists, 4639, 4641–2, 4655–6; thinks that in physiology as in anatomy direct observation is desirable whenever possible, 4638; and that experiments, including some painful ones, 4657, are most important, 4635–7.

Necessity of experiment in teaching.

Physiological handbook.

Thinks the experiments in the Handbook of the Physiological Laboratory should be shown for purposes of demonstration, but to a select class only; students generally have too little time to go thoroughly into the subject, 4650–2; does not vivisect much, and has never exhibited experiments on any animal higher than a frog, but has seen vivisection in Professor Ludwig's laboratory at Leipsic, where the majority of experiments are for research, although there are some for class demonstration, 4653–4; also knows what is being done generally, and of what great advantage experiment has been to physiology, 4609–10.

MR. CHARLES DARWIN.

Although he has never had anything to do with experiments on live animals and does not claim to be a physiologist, 4670, witness has taken a warm interest in the subject, 4661, and is fully convinced that physiology can progress by the aid of experiment on live animals only, the position of the valves in the veins gave rise, for instance, to many surmises with regard to the circulation of the blood, but certainty was only arrived at by vivisection, 4668.

Importance of physiology.

Believes that physiology is destined to confer great benefits on mankind, and that the prohibition of experiments would be a great evil, especially as all but an extremely few experiments can be performed on insensible animals, 4669–71; but at the same time any unnecessary infliction of pain, either by omission to give anæsthetics when possible, or otherwise, deserves detestation and abhorrence, 4672.

Resolution of the British Association.

Cordially approves of the resolutions of the British Association in 1871 with regard to vivisection, 4662–4, and also in the main of Dr. Playfair's bill on the subject, 4662–4.

FRANCIS SIBSON, M.D., F.R.S.

Member of the Senate of the University of London, and consulting physician to St. Mary's Hospital, 4673–5.

The Chloroform Committee.

Has taught the practice of medicine and clinical medicine for some 20 years, 4696–7; performed a few experiments many years since, and subsequently some others with regard to the action of opium, chloroform (as a member of a committee of the Medical and Chirurgical Society,) and as to the movements of the heart, the last of which have been much referred to, 4676–4727–8.

Physiology the foundation of pathology.

Necessity of Vivisection.—Considers physiology is the true basis on which pathology rests, 4706–8, and has found his own investigations with regard to the respiratory organs of use every day of his life since, 4709–10; refers to the importance of various discoveries made by means of experiments on animals, with regard to the antagonism of certain poisons, 4783.

Experiment essential to medical education

Believes it to be as impossible to teach physiology by lectures only as it would be to teach medicine without clinical practice, 4705; considers that the introduction of the practical method of teaching in the various branches of medical science, including physiology, has been the vital improvement of recent years, 4698–704, 4713; the old teaching was no teaching, and the knowledge of anatomy even required by the examiners was very slight indeed, 4711–2.

Anæsthetics.—Considers that the fundamental facts of physiology can be demonstrated on insensible animals, 4714, and that the number of very painful experiments for research is very small, 4744.

Has never heard of anæsthetics having been given for the convenience of the operator only, such a spirit should be repressed, 1718–20.

Anæsthetic effects of disease.

In pathological experiments either anæsthetics can be given or the pain is too trivial to require their use, 4678–80, and in most instances the disease itself acts as an anæsthetic, especially in cases of fever; has observed this effect of disease among the patients in hospitals, 4681–3; observes that the more painful ailments, such as carbuncle, are never made the object of experiment, 4684; and refers to the absence of pain in erysipelas and tuberculosis, 4684, 4730–2.

Schiff, Kolliker, and Claude Bernard.

Mr. Yule's experiments.

Curari.—Does not admit that the desire to believe curari to be an anæsthetic has led to its being so regarded, 4761. Although its first action is on the motor nerves, witness agrees with Schiff in thinking that in sufficient doses it also affects the sensory system, 4752–9. Believes that the conclusions of Kolliker and Claude Bernard go beyond the premises on which they are based, 4762–77; considers that the present position of the question is that there are no grounds from which either the consciousness or unconsciousness of the animal to pain can be logically deduced, and that Mr. Yule's experiments appear to show that curari deadens the reflex action of the spinal chord, 4778–82.

Admits, however, the subject is a moot point amongst physiologists, 4752, and that some to avoid doubt give opium also, 4758, 4779.

Useless experiments.

Regulation of Experimentation.—Is not prepared to admit that abuses have increased in the same ratio as the practice of vivisection itself, 4733–6; does not regard Sir Charles Bell's assertion that a large number of useless experiments were performed in his day as of any weight, as he carried his reluctance to experiments so far that he left some of his great discoveries to be confirmed by the experiments of others, 4737–9.

Sibson, Francis, M.D., F.R.S.

Incompetent experimenters.

Considers that experiments by incompetent persons are useless, but does not believe that abuses are frequent enough to require legal repression; fears that restriction would clip the wings of science, and prefers to leave matters to men's consciences and public opinion, 4688–95; does not, however, object to the Cruelty to Animals Act, 4692.

Humanity of physiologists.

Believes that physiologists endeavour to give as little pain as possible, and "spend no end of pains in planning and preparing" for them, so as to get as much out of them as possible to avoid repetition, 4685–7, 4716–7. Thinks one result of leaving English investigators alone will be to show foreign physiologists that great scientific results can be reached with greater humanity, 4739.

Majendie.

Miscellaneous.—Majendie had an object in every experiment he did, but was a ruthless repeater of them, he seems never to have considered that he was dealing with sentient animals, he might have obtained the same results with less suffering, 4739, 4743.

Mayo.

Mayo's experiments although not great experiments were certainly justifiable, 4740–2.

Exposing animals to high temperature. Boiling frogs to death.

Thinks the suffering caused by raising or by reducing the temperature of the body until death supervenes cannot be very severe, as in either case the animal would soon become unconscious, 4745–9. When the temperature of an animal is raised to 112° or 113° it practically dies, and when it sinks to 70° or thereabouts it loses consciousness, 4784–6. Goltz's experiment of boiling a frog to death is horrible, 4750.

Chossat's starvation experiments.

Considers that Chossat's starvation experiments were carefully planned, and have shown the necessity of a certain temperature being maintained in order to preserve life, 4751; is inclined to think no great pain was given, starvation induces discomfort, extreme cold (which causes pain), and then deadening of the nerves, which stops pain, 4787–9.

Biliary fistula in dogs.

Does not think that the experiment of establishing a biliary fistula in dogs under curari would be very painful even if curari were not an anæsthetic, gives reason, 4752, 4760.

"Frightful" experiments.

Considers medical students like other young men are fond of animals, and that any "frightful" experiment would certainly be stopped by them, 4721–6.

JOHN MALLET PURSER, M.D.

Professor of Institutes of Medicine at Trinity College, Dublin, 4791.

Was educated partly in London, partly in Dublin, 4829; has been a professor at the school of physic two years, but taught in a private school for seven years previously, 4811.

Gives two courses of lectures, one on practical histology, the other on physiology, 4792, and has about 50 or 60 students each year, 4821.

Ill effects of prohibition of demonstration on live animals.

Is considerably impeded in his physiological course by the regulation of the university forbidding experiments on live animals, 4792–3, even when under anæsthetics or when pithed, 4839–43, 4847–9, 4867, 4886; the prohibition does not extend to experiments on animals just killed, 4839–43, 4868, or to tying out a frog's toes to show the circulation of the blood, although that must cause the frog some inconvenience, 4841; if the regulation were repealed, the control of the University authorities would prevent abuse, 4834–5.

Regrets not being able, for instance, to show the influence of the pneumo-gastric nerve on the heart on a pithed frog, 4843, 4851–4; believes the authorities would allow him to cut off a frog's head and then demonstrate it, although he has not asked permission to do so, 4855–76.

Some painful experiments are desirable for demonstration.

Considers that experiments on live animals are necessary for demonstration, the greater number would be under anæsthetics, 4793–99*a*, but some painful ones on the sensitive nerves of warm-blooded animals are desirable, 4793–9*a*, 4832–3; does not believe students would object to any properly conducted experiment even if painful, 4804.

Occasionally gave painless demonstrations himself on live animals whilst teaching privately, and saw a few in the same school when a student, 4826–33, 4881.

No experiments are performed by students at Dublin; thinks they should not be allowed to undertake them except under the direction of the professor, 4812–6, 4835–8.

Private experimentation by students.

Does not believe private experimentation exists among students, and there is no need therefore to forbid it, 4817–20; students have no taste for experimentation, gives various reasons for the fact; believes any desiring to undertake them would come to their professor; believes that the more students know of experimentation the less likely they are to attempt it without due care, 4884–5.

Purser, John Mallet, M.D.

Farm vivisection.

Is aware of the extent of farm-vivisection, but considers its existence is not a valid argument in favour of scientific vivisection, and any law against needless infliction of pain should, however, have a general bearing, 4877–80.

Teachers should not be subject to restraint as to experiments.

Objects to legislation, however, altogether, and thinks that teachers of physiology should be the sole judges as to the propriety of an experiment, 4800–9; his own experience of university restriction causes him to deprecate any further restraint, 4850.

Believes that professors are humane, and that students will not experiment, and considers legislation would be unnecessary and harmful, 4825.

MR. JAMES B. MILLS.

Veterinary Surgeon in the Royal Artillery, 4913, and formerly at college in Edinburgh, 4915.

Anæsthetics.—Chloroform was used at the Veterinary College for very painful experiments, and also for delicate operations to secure steadiness, but not for firing and minor operations, 4962–3, 4967–8; uses it, however, himself for firing if the surface is large, 5046–52; there is no difficulty in giving chloroform to a horse if it be done with care, 5050.

Lithotomy performed on the live animal for demonstration.

Vivisection for Veterinary Demonstration.—Horses and donkeys bought for dissection were kept in a paddock until wanted, 5120–1; and sometimes first used for demonstration, instances a horse in which lithotomy was performed under chloroform and the animal allowed to live 12 or 14 hours before being killed, although he must have suffered considerable pain, 4969–92, 4996; dogs were also used for such experiments, 4981; lithotomy is very rarely performed on the horse, and might have been learnt from the dead subject, 4993–5; also instances a case in which the jugular vein of a pony was opened and the blood blown back and the animal allowed to live for some time afterwards, this experiment was not under chloroform, 4997–5008; in a third instance tenotomy was performed as an experiment on a horse, not under chloroform as the operation is not very painful, 5034–44.

Blowing back the blood.

Tenotomy as an experiment.

These were the only experiments on live animals at the college during the time witness was there, 5053–4; they were all performed by Mr. Williams, the present principal, 5104–6.

Experiments by Students at the College.—Knows that experimentation by students has been going on for five years, and believes it will be continued until put a stop to, 4952–5.

A dog sent by its owner to be destroyed, 5165–6, had some prussic acid given it, 5136–49; it was then partly restored by ammonia, and finally had its brains knocked out by the students, gives details; the professor did not know of this, 5009–31, 5150–5.

Unnecessary painful experiments.

Believes that many unnecessary operations involving great pain are still performed there, refers to an instance which occurred last winter of which all the students, and, he believes, the principal must have known, 4936–46, 4957, 5125–6. A horse suffering from disease of the sensitive laminæ of the feet, 4965, was bought for dissection, 4957, 5122–4, and kept for at least a week in a paddock attached to the college, 4957, 4964, 5108–9, and during that time was experimented on all over, 4966, by the students without, as far as witness is aware, any sort of control, 4950–1, 5107. The horse was neurotomised on both fore feet (which would, however, relieve him from the pain of the disease), 5110–7, 5129–32, then subjected to tenotomy of the perforans and perforatis, and to various minor operations, 4960–1, 5118–9, 5127–8. Anæsthetics were not used and the horse must have suffered a great deal, 4958–9, 5179–80. These operations were done openly in the quadrangle attached to the college (which is not, however, overlooked), 4947–9, 5133–5. Except in this instance witness believes such experiments are not known of by the authorities, 4956–7. Declines to give the name of the gentleman from whom he received the information, 5102–3.

Uncontrolled experimentation by students.

Experiments by Students in their rooms.—In his first term was admitted to at least two meetings for private experiment by students at their lodgings and subsequently to a great number, 4916–23; is sorry to say he operated himself, 4924.

Mills, Mr. James B.

Cat hunts.

Cats and dogs hunted down or caught by a poisoned bait and then painfully restored by antidotes, were used, 4927–31; these experiments were simply to demonstrate known things, 4928; and were due to idle curiosity and a reckless love of vivisection only, 4932.

Poisoned baits.

Was present at five private experiments by students, they usually consisted of opening the thorax to see the heart beat, and of picking up blood vessels and nerves, gives details, the authorities knew nothing of these experiments; about 6 or 8, including two medical students, were present; did not know of any other students making such experiments, 5055–100, 5181–3; in two cases the animal was partially narcotised by the poisoned bait, 5167–72; the house in which these experiments were performed was occupied by three students and the landlady and her husband, 5156–7; the cries of the cat (the landlady's) disturbed the neighbourhood, and witness and the others nearly got into a great deal of trouble about it, 5158–9. Subsequently was lecturer on materia medica, but the time being summer there was no dissection, and consequently no animal to experiment on, 5173–8; has not experimented on animals since he obtained his diploma, 4935; knows nothing of the proceedings of the Veterinary Society of London or of the Medical School of Edinburgh, 5160–4.

The statement in the paper sent by witness to the Royal Society for the Prevention of Cruelty to Animals is an unadorned statement of facts, 4914, 4933–4.

WILLIAM BENJAMIN ARCHIBALD SCOTT, M.D.

Licentiate of the College of Physicians at Edinburgh, and of the Faculty of Physicians and Surgeons of Glasgow, 5184–5.

Has been in communication with Mr. Jesse, 5186.

Circulation in the mesentery of a frog.

Has attended class lectures on physiology and pathology and read standard works on the subject, but has witnessed two or three experiments only, 5188; one of these formed part of the practical course at Edinburgh in June 1871, and was performed by the professor or his assistant, witness was so disgusted by it that he never went again, 5188–91, 5200–3, 5227–8, 5233–4; the experiment—describes it in detail, was the demonstration of the circulation of the blood by the microscopic examination of the mesentery of frogs under curari but not pithed, and which therefore, in his opinion, were suffering considerable pain, 5190–3; admits, however, that it would have been very difficult to have kept the frog under chloroform without curari for so long a time, 5235–6.

Theory as to inflammation.

Considers that the object was in part to illustrate a particular theory of the demonstrator's, 5192, with regard to the formation of the pus cells in inflammation, refers to the theory in detail, the practical importance of the question was simply nothing, except as showing the nature of inflammation, 5221–3; admits, however, that the discovery of the circulation of the blood although at the time a matter of pure science has since borne practical results, 5224–5.

Physiological Handbook.

Curari.

Refers to various experiments in the "Handbook for the Physiological Laboratory," showing that curari destroys or suspends the irritability of the motor nerves but not, as the book observes, that of "the sensory nerves or central nervous system;" also adverts to the absence or insufficiency of directions with regard to anæsthetics, and to the long duration of some of the experiments, 5194; Dr. Sanderson's work shows that curari is used in England although it has been publicly stated that it is not, 5226.

Thinks that the exposition of the movements of the heart, the demonstration of the lymphatic circulation, and similar experiments ought not to be undertaken without an anæsthetic in addition to curari, either in the case of frogs or the higher animals, 5195–9.

Adverts to the duration of pathological experiments, gives examples, 5193.

Experiments by students.

Believes that experimentation by the more zealous students in their own rooms is common, judges that this is the case from their common conversation, but can name only one student who used to so experiment, he operated on frogs, 5238–51.

WILLIAM LEGG, M.D.

Demonstrator of Morbid Anatomy at St. Bartholomew's Hospital, London, 5315–7, 5252.

Method of obtaining the animals for experiment.

Experimentation at Saint Bartholomew's Hospital.—There is no physiological laboratory at St. Bartholomew's, but a private room belonging to Dr. Brunton is used for experiments, 5257–8; knows nothing of the manner in which live animals are obtained for experiment, and has not inquired, 5318–9; before performing an experiment reads up all that has been written on the subject, 5286; and invariably employs anæsthetics where practicable, 5331, 5342; has performed four or five series of experiments, 5255; all of which have had reference to diseases which may occur in man, 5320–2.

Legg, William, M.D.

Ligature of the biliary duct in cats.

Ligature of the Biliary duct in cats, and other Experiments.—Performed a series of experiments on 16 cats as to the effect of the ligature of the biliary duct, 5256, 5259. The number of animals used was larger than in any other series, 5313, but not too large he considers for securing accurate results, 5265–7; believes, judging from human experience, that neither the disease nor the wasting away, nor the other symptoms could have been very painful, 5269–80. The results could not have been obtained by killing the animals after three or four days, 5277; the experiments were however conducted as humanely as possible, 5290–1.

Diabetic puncture.

The uncertainty with regard to the date of death except as regards one cat which strayed away, 5274–5, was caused by his absence on Sundays, he saw them every other day, 5287–9. The diabetic puncture was made under chloroform specially to see its effect on a diseased animal, 5281–3.

The main results were the increase of the connective tissue and the discovery that glycogen is not produced after ligature of the bile duct, both new and important points, 5260–5, 5284–6, 5292.

Observes that liver diseases are very common, some of them are very obscure, and great difference of opinion exists, and it is therefore a subject which it is very desirable to elucidate, 5322–4.

Bile pigments in the urine.

Attempted innoculation of cancer.

Exposure to high temperature.

Witness' other experiments have comprised an investigation as to the cause of bile pigments in the urine in which four animals were experimented on under chloral and killed afterwards, 5311–2; an unsuccessful attempt to produce cancer by innoculation under chloral, 5309–11, 5314; an investigation into the effects of hydrochlorate of cotarnamic acid on three or four dogs and, to his considerable discomfort, gives details, on himself, 5303–8; and some experiments in which the temperature of the body was raised artificially, to ascertain the changes effected in the various organs during fever: the animals, four in all, were under chloral hydrate all the time, and were killed afterwards, 5295–302.

Necessity for Pathological Experiment.—In an examination of the dead human body you have only the débris of the disease, but by experiment on animals and by killing them at different stages you get the complete natural history of the disease, 5325–30; considers that the artificial conditions by which disease is produced do not affect the results, 5339–41; the innoculation is often performed under chloroform, and the pain of the disease, the common lot of most things living, is the only suffering, 5332–4; some diseases bring but little pain, tuberculosis is sometimes painful, but often not, 5335–8.

Believes that experiments are conducted as humanely as possible in this country, 5343–5.

ARTHUR GAMGEE, M.D., F.R.S.

Brackenbury Professor at Owen's College, Manchester, Examiner in physiology at the University of Edinburgh, Examiner in forensic medicine at the University of London, 5346–9, 5372.

Has studied for a short time at the Universities of Leipsic and Heidelburgh, and also in Paris, 5416.

Never performs painful experiments for demonstration.

Gives two courses of lectures, one on systematic physiology for first year's students, in which a few experiments, always under anæsthetics, are performed, 5356; and a practical course for second year's men, in which every painless method of investigation is illustrated, 5356; there are about 40 students in each class, 5384. Details his method of instruction; never performs a painful experiment for demonstration, which he considers may be avoided without detriment, not even those showing the action of poisons, and always destroys the animals before sensibility returns, 5356–7, 5373, 5397–400. Performs experiments before his class with regard to arterial pressure, but always under anæsthetics, 5401–2, and is of opinion that experiment on live animals is essential in teaching, 5386–7.

Has entire control over the physiological laboratory, 5373; never allows experiments unless sanctioned and superintended by himself, 5373; does not allow students as students to perform physiological experiments, 5373.

Properties of vanadium.

The present Platt scholar, Mr. Priestley, a highly competent man, has however made under witness' direction

Gamgee, Arthur, M.D., F.R.S.

a series of experiments as to the action of the poisonous compounds of vanadium, 5374–5; gives details, 5388–92; the results are embodied in a paper which is to be read before the Royal Society, 5385.

Does not believe that a custom of experimenting in private exists among medical students, 5370.

In research the great majority of experiments may be rendered painless, but anæsthetics cannot always be used, gives instances, 5358–66. Observes that in cases of induced disease the animal is usually killed before the malady has run its course, 5367–9.

Private experimentation will decrease.

Vivisection is much too infrequent.

Extent of practice of Experiment on live Animals.—There are very few experimenters in English laboratories, fewer still out of them, 5370; the great delicacy of experiment and the elaborate nature of the appliances now necessary prevent much good resulting from private experiments, 5377, which will decrease, 5421–3; but he hopes that the number of laboratories will increase, 5420, as vivisection is now much too infrequent, 5383. Details the special efforts made at Owens College to encourage physiological research, 5385; and points out that all the most valuable physiological facts have been ascertained by experiment on animals, 5351–2.

Foreign physiologists.

Knows many foreign physiologists, including Professor Ludwig and Claude Bernard, and considers them as humane as any English experimenters; believes anæsthetics are used when possible, although on the other hand unnecessary experiments are performed, 5418.

Not an anæsthetic except in large doses.

Curari.—Gives details of an experiment with curari on two children, 5407–8, and gives reason for believing that in its early stages it is not an anæsthetic, but that in larger doses it does, although possibly not invariably, affect the sensory nerves, 5403, 5407, 5411. Considers that it should not be treated as an anæsthetic, 5413; it is used to eliminate certain disturbing influences, 5412.

Claude Bernard had not performed any experiments on human beings, 5409–10.

Choloforming frogs.

Frogs.—In experimenting on frogs always renders them insensible by decapitating them, in which case he also crushes the head lest sensibility should remain, as is possible in it, 5414, but points out that placing frogs in a very diluted solution of chloroform renders them rapidly insensible, 5415.

Claude Bernard has recently published a book on the use and effects of anæsthetics, 5419.

Incompetent experimenters.

Regulation of Experimentation.—Considers that experiment is in the hands of competent men, and is done humanely and for definite purposes, 5371, and whilst admitting that vivisection by incompetent persons should be forbidden, 5376, believes that there is no abuse in England, 5383, and does not think that legislation as to physiological laboratories is needed, 5376.

Difficulty of saying who is competent.

Cannot consider that reasonable regulations would be a slur on the profession, 5425–7, and is of opinion that a properly worked system of licences would be a great advantage, 5381–3; but is not prepared on the spur of the moment to propose details, 5382, 5396*a*. Hesitates to say where the line should be drawn, certainly ordinary students should not be allowed to experiment; on the other hand any hard and fast line, such as requiring the possession of a medical diploma, would exclude many men who ought to be licensed, especially now that physiology has become a separate study; gives instances, 5378–80, 5393–5, 5404–5.

GEORGE JAMES ALLMAN, M.D.

Emeritus Professor of Natural History in the University of Edinburgh, 5428.

Has never used experiments on live animals for demonstration, 5448, and for private experiments frogs only, 5448.

Action of poisons.

Thinks experiments necessary for the advance of science, 5430–1, but not, if painful, for teaching, 5443; is of opinion that demonstration of the action of poisons is not necessary, the symptoms are so marked and the descriptions are so clear, 5449–51.

Considers that painful experiments should not be repeated unless there be any doubt as to the result arrived at, 5444–6; that anæsthetics should be used whenever they would not interfere with the results, that is in the large majority of cases, 5432–4; that in other cases the operations should be performed under chloroform, even if the subsequent portion of the experiment cannot, 5435–8; and that the animals should be killed after the experiment, if recovery would entail severe pain, 5455–6.

Allman, George James, M.D.

Record of experiments.

Approves in the main of Dr. Playfair's bill, considers it better than Lord Hartismere's, 5439–40; and thinks that a record of all experiments should be kept, 5441–4.

Thinks licensing laboratories and providing for inspection by a competent board would prevent abuses, 5457.

SIR WILLIAM WITHEY GULL, M.D.

Consulting Physician to Guy's Hospital, formerly Fullerian Professor at the Royal Institution, &c., &c., 5458–61.

Transfusion of blood.

Necessity for Experiment.—Considers that experiment is necessary for the progress of surgical and medical science, 5464; points out that our knowledge of dropsical affections, pulmonary apoplexy, engorgement of the liver, and the whole category of such affections, and the possibility of transfusion of blood, flowed from Harvey's great discovery. Refers also to the method of cure for aneurism, and the treatment of spasmodic affections, &c., as results obtained by experiment on living animals, 5525–8.

Vaccination.

Refers to the advantages derived from a knowledge of the processes of inflammation and of tubercle and vaccination, 5529, and observes that the latter has saved more lives than Napoleon's wars destroyed, 5530–2.

Extent of practice of Experiment.—Is glad that the acquaintance with physiological facts is extending over a wider area, but doubts whether there is more vivisection in the way of research than formerly, refers to the time of Harvey as an instance, 5487.

Experiments for Demonstration.—Considers that a certain amount of demonstration by experiment is desirable, but that students ought not to be allowed to perform experiments, 5476–8; the number of painful experiments necessary for demonstration is few, 5505, 5507. Does not consider it often necessary to show the action of poisons by experiments, but every teacher should be allowed to decide such a point for himself, 5507–10, and also whether such experiments as those of Sir Charles Bell on the nerves, which are not now performed before classes, should be repeated; believes, however, that their repetition would excite reprobation both among students and teachers, 5471, 5511–5. At Guy's Hospital about two students only out of 300 attend the physiological demonstrations, 5516.

Anæsthetics.—The great majority of experiments are, as far as possible, performed under anæsthetics, 5466–7; observes that the removal of sensation is very generally necessary to the success of an experiment, 5467; pain complicates and modifies the result, 5469; knows of no experiments in which suffering is a necessary part, with the exception of the very few which relate to the nerves of sensation, 5470.

Believes that careful instruction in a laboratory tends to minimise the infliction of pain; ignorance, not knowledge, is cruel, 5498.

Objection to legislation.

Regulation of Vivisection.—Objects to legislation on the ground that abuses do not exist, and that it would be therefore an undeserved slur on the profession, also because he fears it would check scientific inquiry which would be deplorable, 5472–5, 5484–6; the tendency to rest content with present knowledge is already too strong, 5476. Admits that the existence of an Act against cruelty to animals is not regarded as a slur on the reputation of England, but contends that highly educated men will be restrained by their own humanity where it may be necessary to control the more ignorant by law, 5481–3, although the law applies to both, 5503–4.

Vivisection justifiable on its merits.

Instead of basing his opinion on the fact that legislation in this instance would be class-legislation against physiological investigators, because other sections of the community, who perform operations on live animals, are left untouched, prefers the higher ground, that vivisection is justifiable on its merits, 5495–7, and that there is no abuse of the practice, or experimentation by incompetent persons, to restrain, 5478–80, 5494.

The alleged "maleficent" tendencies of medical students.

Miscellaneous.—Has lived for 15 years in Guy's Hospital with medical students, and been occupied with them for 30 years, and considers the statement with regard to the "maleficent tendencies of medical students" a serious libel on them, and the reference quoted with regard to "frightful" experiments not founded in fact, 5500–2; any cruelty would be scouted by medical students, 5468. Believes that there is a sentiment of humanity among English experimenters, 5465; and doubts whether pure

Gull, Sir William Withey.

physiologists are more careless of suffering than medical men, 5522–4.

The method of research, including the use or non-use of anæsthetics, must be left to investigators, 5506, 5517.

Thinks that a man avowing that the sufferings of an animal under experiment were a matter of indifference to him should be morally controlled, if possible, by the influence of his friends, 5489–92; such indifference is worthy of detestation, an animal's sufferings should be considered as well as human suffering, 5493, and if public opinion should be insufficient to restrain such experimentation, legislation might be needed, 5518–21.

Popular feeling based on insufficient knowledge.

Is of opinion that the popular feeling against vivisection is based on insufficient and incorrect information as to what is really done in England, 5463; and partly caused by a belief that the "mysteries" of life are beyond the pale of legitimate inquiry, 5499.

'Relicta of ancestral relations."

His observation that "should advancing knowledge " show that we have superfluous parts or organs, and " especially if these are liable to disease, what a land of " promise for operations!" made when president of the Clinical Society, was purely hypothetical, and refers to parts which appear to be "relicta of ancestral relations," and which appear to have no direct use; the whole subject of hereditary transmission is very important, and experiments with regard to it should not be forbidden, 5533–44.

WILLIAM BENJAMIN CARPENTER, C.B., M.D.

Registrar of the University of London, formerly Lecturer on Physiology at the Bristol Medical School and at the London Hospital; Author of the "Principles of Human Physiology," the "Principles of General and Comparative Physiology," &c., &c., 5578–82.

Sir C. Bell.

Necessity for Experiment.—Experiment is essential to physiology, the science is based on it, 5601; physiological deductions from anatomical observations can only be tested by experiment, Sir C. Bell, for instance, trusted too much to anatomy, and fell into errors which had to be corrected by other physiologists, 5601.

Practical all knowledge.

John Reid's experiments.

Limits of Experimentation.—Experiments which are likely to increase physiological knowledge should be performed even if severely painful, as for instance, those of Dr. John Reid, with regard to the functions of the *par vagum*, 5603, 5615; no one can forecast the practical advantages which results from the discovery of physiological teaching. Chloroform for many years was merely a scientific curiosity of no practical importance, 5615.

Brown-Séquard.

Even protracted suffering may be justifiable, instances Brown-Séquard's experiments on 40 or 50 animals of various kinds, proving recovery possible after the section of the spinal cord, a thing previously considered impossible; adverts to the practical benefits conferred by this discovery, 5604–5; gives particulars, 5605–14.

Considers that the experiment in which two animals were made to grow together by removing portions of the skin of each and binding them together, might have an important bearing on the treatment of ulcers, 5621–2.

Action of rhubarb.

Thinks the experiment of introducing rhubarb and other drugs into the intestines of a dog and observing its effect on the secretion of the bile a most important experiment, and one which it would be necessary to perform both with and without anæsthetics, 5632–4.

Has known Dr. Brown-Séquard for 30 years, his great reputation for the treatment of nervous disorders was due to the skill he had acquired by means of his acquaintance with physiology derived from experiment, 5635–41.

Painful experiments unnecessary.

Experiments for Demonstration.—Considers that experiments for demonstration are most desirable if painless, but that painful ones, except in teaching toxicology when they are essential, are unnecessary and morally injurious, 5602, 5620.

Frogs.—Frogs have extremely little perception of pain, 5613; believes there is no evidence that they suffer any pain after the section of the spinal cord, 5614.

Purposeless experiments.

Majendie.

Indifference to animal suffering.—Has himself seen a perfect callousness to animal suffering, this was prior to the introduction of anæsthetics, 5627, and is sure that many experiments have been, and are, made simply to see what will happen, 5624–5, 5627; very many of Majendie's were of this nature, 5626–7. Believes, however, that experiments are humanely conducted in this country, 5583–4, and that English physiologists look upon it as a duty to give chloroform when possible, 5628–9.

Carpenter, William Benjamin, C.B., M.D.

Dr. John Reid.

Was intimately acquainted with Dr. John Reid, thinks he may have used some such expressions as those attributed to him with regard to his intense sufferings being a retribution on him, but witness has letters written by him within a few weeks of his death in which he expresses his thankfulness at having been permitted to so far complete his physiological researches, 5630–1.

Doubts the possibility of regulation.

Cock fighting.

The Maine law.

The Anatomy Act.

Regulation of Vivisection.—Effectual regulation without undue interference with the liberty of the subject would be desirable, but its possibility is doubtful, 5585–7, 5596; does not see how any line can be drawn between permissible and cruel experiments, 5594–5, 5644; or how private experimentation can be regulated, 5594; it cannot be put down like cock fighting which must attract attention, 5598, and even that, is more likely to be stopped by a healthy public opinion than by law, 5600; refers to the analogous case of the Maine law which witness thinks rather increases than prevents drinking in private houses, 5598–9, and points out that, although under the Anatomy Act dissection of human bodies except in licensed places is forbidden, cats and dogs and parts of human bodies are constantly dissected in private houses, 5597.

Dr. Playfair's bill.

Considers that it would be most undesirable to forbid experiment on living animals when deprived of sensation, 5642–3; has not studied the details of Dr. Playfair's bill, but fears there would be grave difficulties in working it, 5594.

Introducing boiling water into the stomach of a dog.

Miscellaneous.—The narration of an experiment in which boiling water was introduced into the stomach of a dog in witness' work on physiology was not inserted by witness, but was introduced in a late edition, would not like to offer an opinion about it without knowing its object, 5620.

The Brown Institution.

The funds of the Brown Institution are held in trust by the University of London for maintaining it as an institution for the study and cure of maladies and injuries of animals serviceable to man, 5645–6; and, under a recent legal opinion, for the performance of pathological experiments, 5648–50. Some other points connected with the administration of the trust have been inquired into, but will not be dealt with by the senate until the Commission have reported, 5647, 5651–4.

THOMAS LAUDER BRUNTON, M.D., D.Sc.

Lecturer at St. Bartholomew's Hospital on materia medica, 5655, 5692.

Gives about eight or ten lectures a year, 5702–3. Makes considerable use of experiment in investigation with regard to the action of drugs. Invariably destroys animals after the experiment, 5801–2; his laboratory is too small to allow any spectators except the man who is helping him, 5799–800.

Calabar bean.

Pharmacological Experiments. — Pharmacology has developed rapidly of late, 5667, and many valuable remedies have been discovered by experiment on animals, 5666, 5668; chloral, atropia, apomorphia, and the Calabar bean have been added to the stock of useful drugs, 5670.

Carbonic oxide and carbonic acid gas.

Investigation as to the action of drugs.

Refers to Bernard's discovery by experiment of the difference in the cause of death in poisoning by carbonic oxide and by carbonic acid gas, and to Hüter's employment of this knowledge and consequent saving of life, 5670–4; also to the mitigation of suffering in angina pectoris, consequent on his own observations with regard to the action of nitrite of amyl, 5669; operations are often necessary to discover on what part of the body and how the drug acts, they are nearly always done under anæsthetics, 5660–2; pain resulting from the operation seldom occurs, 5687–8, and is probably of small amount, 5687–80; the chief pain is from the action of the drug, 5664–6, which often has to be observed after anæsthesia has passed away; sometimes, however, the drug can be allowed to act under chloroform, and an allowance made for its influence, 5675–7.

Supply of animals.

The number of animals required in experiments for research varies enormously, 5720; has himself used in all about 150 animals of different kinds, 5748–9, chiefly cats, because they are a convenient size and cheaper than rabbits, dogs cannot be got, asks no questions as to how the cats are obtained, 5731–5; has never had occasion to sew up their lips, 5736.

Nitrite of amyl.

Next to the snake poisoning experiments, his investigation with regard to nitrite of amyl and other substances rank in point of importance, but the number of animals consumed was much smaller, the results being of a marked character, 5751–2; chloroform was not used as it would have very much complicated the experiments, even if used only during the actual operation its residual action would have interfered with that of the amyl, 5753–9.

Cholera.—Used 90 cats in the first series of investigations with regard to cholera, describes the method pursued, and gives reasons for it, 5721–7; no beneficial discovery has yet been arrived at; the experiments are still proceeding, 5728–30, is now at the third series of them, 5747.

Snake-poison.—Believes that an antidote can only be discovered by experiment, and has recently been engaged with Dr. Fayrer in investigations with this object, 5689, and used a large number of rabbits, guinea-pigs, frogs, dogs, pigeons, and fowls, but not so many animals in all as in the experiments with regard to cholera, 5746–7.

The animals were innoculated with the poison, 5750, which witness considers the most powerful thing with which he has experimented, it kills an animal in about half an hour, describes the symptoms, 5681–4; doubts whether the pain caused is as great as in poisoning by strychnia, although the convulsions in the latter case may possibly not be painful, 5685–6, anæsthetics cannot be used, 5683.

Hydrophobia. Has never experimented with regard to hydrophobia; it would be a difficult subject, 5690–1.

Experiment essential. Prussic acid. **Experiment for Demonstration.**—Considers that ocular demonstration is essential in teaching, gives reasons, adverts to poisoning by prussic acid and to the facility with which any one who has seen its action on an animal can recognize and deal with it in a human being, 5716–7; at present this is the only experiment witness performs without chloroform, 5704–7; uses rabbits and cats for these demonstrations.

Poisoning by carbonic oxide or carbonic acid gas is believed to cause no pain, the pain is in the recovery, but is not probably great, 5710–5.

Picrotoxine. Strychnine. The action of organic poisons such as strychnia and picrotoxine is at St. Bartholomew's shown by the lecturer on forensic medicine, 5708–9; the pain is much the same under either, 5814; does not think the action of strychnine can be properly shown under chloroform, which has in fact been used as an antidote to it, 5803; gives further reasons, 5813.

St. Bartholomew's. **Anæsthetics.**—In the reply to the Commission from St. Bartholomew's Hospital with regard to the use of anæsthetics, it should have been stated that anæsthetics were used whenever possible, 5693, 5700–1.

Chloral. It is not safe to give human beings chloral in sufficient quantities to produce anæsthesia, animals do not recover from large doses of it, 5769–70.

Opium. Opium is an anæsthetic, but it disorders the system to a much greater extent than chloroform, and is therefore more dangerous, 5771–5.

Insensibility under narcotics. The assertion, that "in the deepest narcotism produced by morphia or opium, there is no real insensibility to pain," is certainly erroneous, 5804–8; nor is there anything tending to prove that pain is felt but forgotten, or that narcotized animals are sensible to pain, 5809–10.

Describes the means by which cats, dogs, and frogs are put under chloroform, and observes that there is no difficulty at all about doing it, 5737–9.

Curari.—Considers curari is to some extent an anæsthetic, 5693–5, gives reasons, 5696, and refers to Von Bezold's, Schiff's, and Lange's experiments as tending to show this, 5791–5, and observes that after recovery from its effects animals do not show signs of having felt pain, 5796; but admits that its exact properties are involved in uncertainty, 5693–7. In demonstrating employs it for frogs only, 5698–9.

Its effect on the sensory nerves. It can be demonstrated on frogs, especially in spring, that curari affects the sensory nerves, 5699, 5791, and it is probable it also affects the higher animals, 5796. Cannot say whether the scientific world generally takes this view, 5797–8.

Its uses. Considers that curari, in addition to keeping the animal still, also eliminates some of the sources of disturbance resulting from the irritation of the nerve-centre, gives example, 5742, 5744; believes that in some experiments curari is necessary, in others chloroform, administering both is often impossible, gives reasons, 5741–5; doubts whether chloroform could have been used in Dr. Rutherford's experiments on the liver, it would probably have produced nervous congestion in that organ, the curari used would somewhat affect the secretion and would have to be allowed for, 5760–8.

Handbook of Physiology.—Refers to several experiments in the handbook of physiology which are stated to be

"suited for demonstration," and observes that with the exception of two in which there is slight pain, and one in which anæsthesia is allowed to partially pass away that these experiments are painless, 5776–90.

In the experiment demonstrating the functions of the chorda tympani, chloroform prevents some points being demonstrated which could be shown under curari, 5811.

ALEXANDER JAMES SINCLAIR, M.D.

Fellow of, and Examiner at, the College of Physicians in Edinburgh, and formerly Demonstrator of Anatomy at the School of Medicine in Edinburgh, 5817–8.

Has never demonstrated on live animals, 5849–50 but in the course of his investigations witness has used about 30 or 40 frogs, which being only to a small extent capable of feeling pain, were not anæsthetised, 5900–4; they were, however, pithed when possible, 5847–8; some of his pupils were present at these investigations, 5851–3.

Witness' experiments as to the inhibitory action of the nerves on the secretions were tried with and without anæsthetics, but the results being the same, anæsthetics were used subsequently to save pain, 5829–32; they would have been used from the first had there not been a doubt as to the result, 5905–6. Inhibitory action of the nerves.

Anæsthetics.—More frequently uses anæsthetics than not, finds them convenient, 5825; believes that pain is minimized and anæsthetics used as far as possible at Edinburgh, 5833, 5839–40; the general opinion would be against any departure from this course, 5909–10; has generally used anæsthetics in experiments, they keep animals quiet as well as save them pain; believes they are generally used on the latter ground, 5826–8.

Knows nothing of the Veterinary College at Edinburgh, 5834–5.

Experimentation by Students.—Had a casual conversation in 1869 with Dr. Hoggan, then a student, with regard to a theory, *primâ facie* not a very probable one, that the distention of the lungs was caused by the force conveyed by the blood from the heart, in the course of which witness recommended him to test it practically by experiment, 5854–77; considers that as a teacher he was simply doing his duty in giving such advice, 5885–92. Cannot say whether chloroform would have interfered with the experiment, 5899, but if the result were against Dr. Hoggan he would very likely have thought it had, 5907–8; witness would not have considered it wrong to perform it without, 5898, but did not make any reference to the use of anæsthetics in his conversation with Dr. Hoggan, 5821–4. Advised him not to use cats because it is difficult to manage a strange cat before it is chloroformed, 5822, 5893–7. Dr. Hoggan's theory of respiration. Cats.

Young men who display ability and a desire to investigate are encouraged to do so, and embody the results in theses, and for these, when meritorious, medals are awarded, 5878–84. Encouragement of research by talented students.

Regulation of Vivisection.—Objects to inspection on the ground that it is needless, 5836–8, 5911, but does not deny that if experiments are being conducted by inhumane persons it would be desirable, and, he believes, desired by scientific investigators, 5912–3.

PETER DAVID HANDYSIDE, M.D., F.R.S.E.

Lecturer on Anatomy at the University of Edinburgh, Examiner in Anatomy, Physiology, and Surgery at the Royal Colleges at Edinburgh, and at the University of St. Andrew's, &c., 5914–7.

Teaches anatomy during nine months of the year, 5918; took part in originating the Society for Prevention of Cruelty to Animals at Edinburgh in 1839, and was for three years its secretary; sees nothing in vivisection inconsistent with the object of that society, 5923, 5937.

Frogs.—Considers that frogs when subjected to painful experiments should certainly be anæsthetised, 5990–2, or have, as in Edinburgh, their heads cut off, 5986–9.

Anæsthetics.—Physiologists always use anæsthetics when possible, 5975, does so himself, 5957. All experiments at Edinburgh are performed as humanely as possible, 5928–9, 5931. Humanity of experimenters.

Never met with any man such a monster as to assert that he used anæsthetics not to save animals pain, but to save himself trouble, 5976.

Has had no experience with regard to curari, 5993.

Experiments for Demonstration.—Describes in detail the method of demonstrating the circulation of the blood Circulation of the blood in the web of a frog's foot under the microscope, and characterises it as a necessary and painless experiment, 5932–4.

Instances other desirable and painless experiments on newly killed frogs, and gives particulars as to the duration of mobility after death or severance from the living body; the tail of a large watch dog, for instance, exhibited irritability for 20 minutes after being cut off, 5930, 5936.

Advance of science.

Necessity for Experimentation.—Considers physiological and toxicological experiments essential for the advance of medical science, which he regards as still in its infancy, 5949; believes the profession generally is of the same opinion, 5949–50, 5952.

Great results of experiments.

Refers to the discovery of the anæsthetic use of chloroform, of Marshall-Hall's method of resuscitation from drowning, of the reproductive functions of the periosteum, to the advantages resulting from Sir Astley Cooper's, Sir David Barry's, Mr. Syme's, and Sir Benjamin Brodie's experiments, and to the practical bearing of his own observation on the portal circulation, and the parts played by the lacteals, the lymphatics, and the veins in the absorption of poisons, 5951.

Experiments by medical men on themselves.

Refers in detail to the various investigations and researches in which he has taken part, and argues that the advantages resulting from such experiments justify vivisection, while the fact that the lives of several eminent men have been all but sacrificed in making experiments on themselves, which might have been performed on the lower animals, shows its necessity, 5994; in short, experiment is the basis of medicine, 5951.

Would not be a "slur" on medical men.

Regulation of Vivisection.—Does not object to legislation, 5938; thinks there would be no more "slur" felt under legislation with regard to vivisection, than there is with regard to the clauses of the Anatomy Act prescribing three months imprisonment for infringing its provisions, 5962–3.

Licences.

Approves of licensing persons desirous of undertaking original experiments only, but teachers should be free to repeat painless fundamental experiments once before each of their classes, and also to perform private original experiments under anæsthesia, 5940; Considers that persons should be recommended by two laymen, such as justices of the peace, and their ability certified by a teacher of the profession, 5940, the laymen to represent the public in the matter, 5941–2; considers that laboratories should be also licensed or registered, 5940, 5942; believes that very few would apply for a licence: to a great extent popular excitement on the subject has no basis, 5948.

There should also be three professional inspectors with duties analogous to those of the inspector of anatomy, 5943–8.

Dr. Hoggan's theory of respiration.

Experimentation by Students.—Rather opposed than agreed with Dr. Hoggan in his theory, but advised him as an intelligent student of whose ability he had had many proofs, to test it by experiment, and offered him facilities for so doing, nothing was said about anæsthetics, it was taken for granted they would be used, 5919–27, 5981–5; at the time witness advised Mr. Hoggan to undertake these experiments, he had become so expert at anatomy that he had been made demonstrator, and witness had great confidence in his intelligence and ability, gives details, 5964–70; refers to other details connected with Mr. Hoggan's account of his conversations with witness, 5977.

Ability of Dr. Hoggan.

It is a matter of notoriety at Edinburgh that students showing scientific aptitude are recommended by their teachers, and rightly so, to embody the results in the theses which they present, 5971–3.

Experiments by students not frequent.

Dr. Hoggan is wrong in saying that "it was common for medical students to try private experiments" with the knowledge and concurrence of the lecturer, witness never knew of any such case, 5953–5; with the exception of Mr. Hoggan, believes that he never advised any student to experiment, 5978–80, during the whole of the 26 years during which he has taught, 5958–61; any student proposing to make a research involving an experiment on a live animal would certainly be told to go back to anatomy first, if he were not competent to experiment from ignorance of that subject, 5971, 5974.

MR. WILLIAM WILLIAMS.

Principal of the New Veterinary College at Edinburgh, 5995.

Experiments by students.

Neither witness, 5996–8, 6132, nor any of the professors knew anything of the operations referred to by Mr. Mills (*question* 4949), 6049–52, 6111, until his evidence was taken, 6109; has since ascertained from a groom who was present, 6064–9, 6110, that something of the kind took place, 5996–6000; gives details, but Mr. Mills' account of it is somewhat exaggerated, 6026–33. Gives particulars with regard to the maintenance of discipline and responsibility for the proper treatment of animals, 6045–52; cannot say how long this particular horse was kept and operated on, 6023.

Can only account for these experiments being unseen by supposing they took place during the Christmas holidays, 6016–22, 6130–1, when the professors are mostly away, 6150–3.

Are very unusual.

Such practices have not been going on for five years, 6007–8; it is the only case, witness believes, which has ever occurred, 6001–3, 6053–4. The experiments were entirely contrary to the rules, 6025, 6047–8. Such an operation as tenotomy is never permitted on a horse bought for dissection, 6102–6; had these experiments been discovered witness would probably have expelled the students concerned, 6042–4; the regulations, however, might be amended with the view of stopping such proceedings in future, 6004–6; knows nothing of the private experimentation and cat hunts referred to by Mr. Mills, 6144–5.

Cat hunts.

Students are compelled to dissect so many subjects, which they buy themselves, each session, 6038, 6112–4; the animals bought are treated with humanity, 6055, and as a rule are killed the same day, 6036; never performs experiments on cats or dogs, and believes they are never experimented on by the students, 6015.

Operations to acquire facility in bleeding.

The students are allowed to bleed from the jugular veins of animals bought for dissection, but that is all, 6024, 6034–41, 6115–6; does not think they are inclined to perform other experiments, 6141, or that they act otherwise than humanely towards animals, 6146. Except bleeding—which it is essential that students should be able to perform expeditiously, 6033, no experiments are undertaken for the sake of acquiring dexterity, 6149; bleeding being so painless and trivial an operation it is not done under superintendence, 6033, 6140–1.

Lithotomy under chloroform for demonstration.

When animals are bought for dissection lithotomy, under chloroform, 6119–24, is the only operation performed for demonstration on them whilst alive, 6009–14, 6125–9, 6082–3; after the lithotomy the animals are killed; in one instance, referred to by Mr. Mills, a horse was allowed to live some hours, gives particulars, 6142–3, to disabuse the students of the idea that it was impossible for horses to recover from the effects of chloroform, 6057–62; it did not suffer great agony, and was able to eat, 6063. In filling up the return sent to the Commission this experiment was from forgetfulness not included as an experiment for demonstration, 6084–6. Lithotomy is a very rare operation; it may save a horse's life, 6117–8.

Tenotomy.

Does not recollect ever performing tenotomy on a horse bought for dissection, 6078, 6096–101, 6107. The horse in which the jugular vein was blown was not, as Mr. Mills states, allowed to live for some time before being destroyed; it died in about 30 seconds, 6070–5. The object of the experiment was to show that allowing air to enter a vein was dangerous, and that blowing the jugular vein was a speedy means of destruction, 6076–7.

Blowing a vein.

With the exception of bleeding and lithotomy no experiments have been performed within the college for a great number of years, 6129.

Anæsthetics.—Anæsthetics are always used when lithotomy is performed experimentally, 6056; does not perform tenotomy under chloroform, the pain being so slight, 6079–81, 6091; sometimes chloroforms a horse for firing him, 6087, but giving horses chloroform is very difficult, they struggle so severely, 6088–90. Neurotomy being a short although painful operation, witness does not as a rule give chloroform for it, 6092–5.

Neurotomy.

Miscellaneous.—Has been told that the phrase, experiments for purposes of "causation," used by the examiners of the College of Veterinary Surgeons had reference to the doings at Alfort, but does not understand its meaning, 6133–9.

EDWARDS CRISP, M.D.

The results arrived at by vivisection are over-rated.

Vivisected animals for several years; gives particulars; believes the advantages resulting from the practice are much overrated, 6157. Gives instances of erroneous conclusions arrived at by this means, and of the opposite opinions based on these experiments; thinks these facts show the uselessness of much of the experimentation going on, and the desirability of some control, 6157–9; believes also that the pain after the operation is often dvocates estriction, ot abo-tion.

left out of consideration; vivisection should not, however, be stopped, 6157–8. Refers to some discoveries of his own which would not have been obtained if vivisection had been forbidden, 6158; thinks a committee should be formed at each hospital to control experiments and prevent useless ones, 6157; believes emulation is the prevailing incentive in vivisection, 6158; but admits that all vivisectors have thought that they were benefiting the human race, 6161. Refers to vivisection by eight students at once, at Alfort, and other experiments, 6157.

JAMES MADEN HOLT, M.P.

he Society or the bolition of ivisection.

Is a member of the committee of the Society for the Total Abolition of Vivisection, but has not attended any of its meetings, and has only communicated with other members by post, considers that the organization of the society is not at all satisfactory, 6162–71; and had he not been ill, would either have succeeded in reforming it or retired, 6287; it needs the appointment of an executive committee who can take active control and meet frequently, shall retire from the committee unless this is done, 6202–3.

ts defective rganiza-ion.

Believes the society was started in consequence of its being felt that the Society for the Prevention of Cruelty to Animals was somewhat slack in moving in the matter; believes the society is largely supported by the public, cannot give particulars, 6177–85, but will obtain them, 6241. Cannot say when the society was formed, joined it in March last from seeing its advertisement, it has no office, and he believes there has been no meeting of its members, nor as far as he knows of the committee; it has no paid officers to get up details with regard to vivisection, but a sort of prospectus of the objects of the society has been published, 6223–36, 6261–2, 6265.

Informal meetings.

Appointment of fficers.

Statements made on its behalf.

Has never attended or been summoned to any meetings of the committee, 6273–5; but there have been informal meetings of two members of the committee and Mr. Jesse, 6281–4. Cannot say how or by whom the president or committee was appointed, 6263–4; it may have been arranged by Mr. Jesse, 6280–1. Believes Mr. Jesse is treasurer and secretary; is not aware that any auditors have been appointed, 6268–70. Knows nothing of any authority having been given to Mr. Jesse to speak on behalf of the society. The letters which have appeared have been rather from Mr. Jesse personally than from the committee, 6237–40. Knows nothing of the letters laid by Mr. Jesse as "the society's representative" before the Commission as far as witness is aware, neither they, nor those published by Mr. Jesse, were written under the authority of the committee, 6276–9. Has himself given no formal sanction to any of the printed documents published by Mr. Jesse, 6285–6.

Entirely objects to the practice of vivisection.

Vivisection Unjustifiable.— Contends that no alleged benefit can afford sufficient sanction for the practice, 6204–6, 6252, inasmuch as it goes beyond the terms of the divine grant of animals for the use of man, and is contrary to the spirit of scriptural teaching, 6175, even if resulting in discoveries which would save thousands of human lives, 6209–11. Considers that the grant sanctions the infliction of pain on an animal in training it for instance, but not vivisection, 6207–8. Admits that the infliction of pain by the scientific investigator in the hope of benefiting human beings should be regarded with less aversion than that inflicted by the sportsman, but points out that in the latter case the animals are used for food, 6212–22.

Overloading an animal is illegal but not cutting him up alive.

Thinks it wrong that while a man may not overload a donkey, even if it be necessary to sustain the bodily life of his family, vivisection may be undertaken for the sake of finding means to heal them, especially as it is of very uncertain value, and medical men are not agreed on the point, 6175.

Thinks vivisection introduces non-natural conditions, and that the phenomena produced are therefore not to be relied on, 6176. Objects as a rule to inflicting pain on one animal in the hope of benefiting others as unjustifiable, but exceptional cases, such as those instanced, should be dealt with on their merits, 6254–60.

The three great discoveries ascribed to vivisection were made by anatomical research.

Refers to the three great discoveries alleged to have been made by vivisection; viz., the discovery of the circulation of the blood, of the double function of nerves of the spinal cord, and that of chloroform, and quotes observations by Harvey and Sir C. Bell to the effect that they made these discoveries by anatomical research, and only resorted to vivisection to demonstrate them to others; observes that the use of chloroform was discovered by Sir J. Simpson's experiments on himself, 6175–6. Has not, however, from illness, consulted either Bell's or

Harvey's works with regard to their real opinion with regard to vivisection, 6172–4, 6243–4, 6288–92.

Hardening effects of vivisection.

Thinks the practice of vivisection, even under anæsthetics, has a hardening effect on the community at large, and specially on medical men, would himself distrust a medical man who vivisected; gives and discusses reasons, 6293–9, and there are persons who will not employ such a one, 6176. Believes that the eminent medical men, who have stated before the Commission that they have practised vivisection, will in consequence not be consulted again by many of their former patients, 6193–5. Would not himself like to be treated by a man who had drawn his knowledge from vivisection, 6253; thinks no humane person would, 6176, even in case where a peculiar knowledge had been obtained, such as that of Dr. Brown-Séquard, with regard to diseases of the nervous system, 6319–22. Fears lest the practice of experimentation on suffering may lead to abuses, 6323. A man who would inflict great pain for eight or nine hours on a dog in order to test the action of a drug might make a similar experiment on man, 6324.

Vaccination.

Inclines to the belief that anatomical students grow somewhat callous in their treatment of dead bodies, 6299–300. Thinks studying books on vivisection likely to exert a hardening effect on the mind, and objects to such a method of medical education; but is not prepared to say that he would refuse to avail himself of the knowledge a medical man had obtained by studying such books, 6247–51; fears that vivisection and vaccination will get mixed up in the popular mind, and that considerable agitation will be the result, 6176; and that if the practice of vivisection is continued, that some of the privileges enjoyed by medical men will be called in question, 6176, 6302–3.

Non-scientific vivisection.

Does not think that it is justifiable to castrate lambs and spay sows for the sake of being able to fatten them more easily, and considers trapping rabbits, and thereby inflicting many hours suffering on them, very cruel, 6310–4. Does not approve of class legislation, but would like to see a measure dealing with the cutting of animals generally, whether for scientific or non-scientific purposes, 6199–201, 6304–9, 6315–7.

Legislation.

Is aware that the Society for the Prevention of Cruelty to Animals has sanctioned a bill tolerating vivisection under anæsthetics, but does not consider that sufficient, believing the experiments would not be conducted without pain, 6186–92, but that the law would be evaded; adverts to the temporary action of all, and doubtful effects of some, of the drugs regarded as anæsthetics; and observes that even if their effectual use were insured. in many experiments they could not be used, 6176.

From general reading, gathers that there is a considerable amount of consent that restrictions on vivisection for teaching purposes are desirable, 6301. If abolition is decided against, is not prepared at the moment to offer suggestions as to its restrictions, 6196–8.

MR. GEORGE HENRY LEWES.

Is not a member of the medical profession, but received a medical education and has studied physiology, especially during the last 20 years, for the most part in foreign laboratories, 6325–8, 6334, 6353.

Experiments on the domestic animals.

Has performed a great many experiments, 6354, nearly all relating to the nerves, 6365, mostly on frogs and other cold-blooded animals, 6357, and not more than a dozen rabbits and pigeons in a dozen years under anæsthetics, 6361–4; always kills the animal after the experiment if it is likely to suffer much pain, 6367. Could not himself bear to experiment on dogs or cats, 6360, 6379, rabbits would nearly always do instead, 6413–7.

Boiling a frog alive.

Very rarely performs an experiment causing pain, 6358, but instances one, 6386–92. Has not performed Goltz' experiment of boiling a frog alive, but has dipped a pithed frog into boiling water to disprove his conclusion, 6380–1.

Consideration for animal pain is much greater in England than abroad, especially than in Italy and Spain, 6372–3; does not think there is any danger of indifference increasing with the growth of experiment here, our national morality has been more cultivated in that direction, 6376.

Vivisection a necessity.

Useless experiments.

Vivisection is a painful necessity, 6330; wishes there were more thoughtful experimenters, especially in England, 6354–6, and fewer needless experiments, 6374; but is aware that a great deal of experiment is quite useless, and cannot possibly prove that which it attempts to prove, and that the disturbances caused by the experiment often invalidate the result, and that phenomena really due to one cause are ascribed to another, gives instances, 6330.

Experiment by students.

Doubts whether experiments on live animals are undertaken by incompetent persons, 6339. Experiment is very troublesome and tiresome, and students have not generally sufficient interest in it to undertake it; gives an instance of the lack of interest taken by students in scientific matters not coming into their examinations, 6339–41.

Untrained students should be made to feel the difficulty of getting satisfactory results rather than—except in the case of students of a really scientific bent—encouraged to experiment, 6341–2.

Useless repetition of experiments.

Before a painful experiment is undertaken it should be clear that a valuable result is probable, 6330, 6347; experiments to see what will happen are preposterous, 6348. Considers that there is much useless repetition all over Europe whenever a new experiment is published; repetition is justifiable only when there is doubt as to the result, 6330, even if the pain is small, 6345.

Experiments for demonstration.

Considers that experiments on live animals are objectionable in medical education, except in a few cases in which they must be seen, 6411–2.

Distinguishes between sensibility and the sensation of pain.

Sensation of Pain.—Thinks pain is quite as special a form of sensibility as hearing, seeing, or tasting, and may in some animals co-exist with other forms whilst in others it may be absent, 6383, 6396–400, 6403; refers to cases and conditions in the human being in which general sensibility exists without sensibility to pain; points out that savages feel pain less than civilized men; gives instances to show that animals with serious wounds cannot feel much pain, and argues that frogs, fishes, and reptiles, have no sensibility to pain, 6345–6, 6382–5; discusses the amount and kind of sensibility remaining in man after section of the spinal cord and under curari, 6405–9. Believes motor impulse essential to conscious sensation, 6370, 6410. Sensibility exists in all reflex

action, and in pithed frogs, but not the capacity to feel pain, 6393–402.

Thinks the amount of suffering caused by vivisection is very small, the pain is in the wounding not the wound, 6345.

Anæsthetics.—Gives frogs ether instead of chloroform, as the latter kills them, 6359; for warm-blooded animals uses ether, chloroform, or chloral, 6366, but never curari, which he regards, however, as a true anæsthetic, 6368–71.

One of the greatest experimenters abroad told witness that he always used chloroform, but simply for the sake of his own convenience, 6376–8.

Desire stopp abuses

Regulation of Vivisection.—Admits the right of society to restrict the right of experimenting on live animals to competent persons, 6331–4; and would be glad to see the present useless repetition of experiments all over Europe stopped, if it could be done without interfering with the prosecution of science, 6345; fears that real physiologists might be excluded if only those who were generally recognized as such were permitted to experiment, he should himself have been excluded by such a rule, although he believes there are very few medical men who have done more physiological work than he has himself, 6334.

but th it mus effecte public opinio rather by la

Does not know of any country having legislation, 6252, and thinks it is utterly impossible to legislate satisfactorily, on the subject, 6330; considers that vivisection, like literary criticism, is a benefit to society, and although both cause pain and are liable to abuse, thinks they can be controlled more effectually by educated public opinion than by legislation, 6334–8, 6349–50; restriction must come from professors inculcating a sense of responsibility both as regards animals and as regards science which is now encumbered with much useless lumber, 6345. If professors would explain to students the excessive difficulty of getting results, useless experiments would decrease, 6330, 6342.
